

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

### Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

### About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

| 8. Index, . . . . .                                                                                                                                                                  | 785  |

# GENERAL REPORT.

---

The following report comprises the general work of the State Board of Health of Massachusetts for the year ending Sept. 30, 1893.

The following are the subjects embraced in this report : —

REPORT TO THE LEGISLATURE UPON WATER SUPPLY AND SEWERAGE, INCLUDING THE ADVICE OF THE BOARD GIVEN UNDER THE PROVISIONS OF CHAPTER 375 OF THE ACTS OF 1888.

SUMMARY OF WEEKLY MORTALITY RETURNS FROM CITIES AND TOWNS.

REPORTS OF INFECTIOUS DISEASES.

REPORTS UPON FOOD AND DRUG INSPECTION.

INFECTIOUS DISEASE HOSPITALS.

HEALTH OF TOWNS.

The following members comprised the Board in 1893 : —

HENRY P. WALCOTT, *Chairman*.

FRANK W. DRAPER.

HIRAM F. MILLS.

ELIJAH U. JONES.

JOSEPH W. HASTINGS.

GERARD C. TOBEY.

MORRIS SCHAFF.

J. H. Raymond resigned in January, and G. C. Tobey of Wareham was appointed in his place.

General Schaff resigned in August, 1893, and J. W. Hull of Pittsfield was appointed in his place.

Dr. Elijah U. Jones of Taunton died in November, 1893. He had been a member of the Board since its reorganization in 1886, and had taken a deep and continued interest in the work of the Board from the beginning of his connection with it.

C. H. Porter of Quincy was appointed in February, 1894, to fill the place made vacant by the death of Dr. Jones.

From these notices the following statistics are compiled for the nine years ending with 1893 :—

*Small-pox in Massachusetts, 1885-1893.*

| YEARS.    | SMALL-POX.   |               |           | VACCINATED. |         |           | UNVACCINATED. |         |           | DOUBTFUL OR UNKNOWN. |         |           |
|-----------|--------------|---------------|-----------|-------------|---------|-----------|---------------|---------|-----------|----------------------|---------|-----------|
|           | Total Cases. | Total Deaths. | Per Cent. | Cases.      | Deaths. | Per Cent. | Cases.        | Deaths. | Per Cent. | Cases.               | Deaths. | Per Cent. |
| 1885, . . | 32           | 11            | -         | 7           | 0       | -         | 13            | 9       | -         | 12                   | 2       | -         |

| 1887, . . | 13           | 4             | -         | 6           | 0       | -         | 5             | 2       | -         | 2                    | 2       | -         |
| 1888, . . | 32           | 5             | -         | 15          | 1       | -         | 13            | 3       | -         | 4                    | 1       | -         |
| 1889, . . | 15           | 3             | -         | 11          | 1       | -         | 3             | 1       | -         | 1                    | 1       | -         |
| 1890, . . | 6            | 1             | -         | 2           | -       | -         | 2             | -       | -         | 2                    | 1       | -         |
| 1891, . . | 5            | 1             | -         | 1           | -       | -         | 3             | 1       | -         | 1                    | -       | -         |
| 1892, . . | 19           | 2             | -         | 7           | -       | -         | 10            | 1       | -         | 2                    | 1       | -         |
| 1893, . . | 44           | 6             | -         | 11          | 0       | -         | 27            | 6       | -         | 6                    | 0       | -         |
|           | 168          | 34            | 20.2      | 61          | 3       | 4.9       | 76            | 23      | 30.3      | 31                   | 8       | 25.8      |

*Summary.*—There were in all 168 reported cases in the nine years (1885-93), and 34 deaths, or 20.2 per cent. of the whole.

Of this number 61 were vaccinated, and of these 3 or only 4.9 per cent. died.

The unvaccinated were 76 in number, of whom 23 or 30.3 per cent. died.

There were also 31 in whom the facts as to vaccination were doubtful or not reported, and of this number 8 or 25.8 per cent. died.

By this it appears that the vaccinated had, as compared with the unvaccinated, a six-fold immunity from death by small-pox, which corresponds fairly with other observations upon larger numbers. To this statement it should be added that in very many of the cases recorded as vaccinated, and especially among adults, there had been but one vaccination, and often a single scar only, and that of an imperfect character.

The following table contains the principal items gathered from the reports of cases of small-pox made to the State Board of Health under the provisions of chapter 138 of the Acts of 1883 during the year 1893.

*Record of Cases of Small-pox reported to the State Board of Health during the Year 1893, under the Provisions of Chapter 133 of the Acts of 1893.*

NOTES.— 1, 2. Vaccinated about seven months since. 4 and 5. Vaccinated unsuccessfully when a child; no further attempt was made. 9. Vaccinated twenty-four and eighteen years ago, and had varioloid. 9. Contracted from No. 3. 12. Vaccinated six years since. 14. Vaccinated twenty-five years ago; one small scar. 15. Vaccinated ten days before. 17. Imperfect scars. 19. Vaccinated in infancy; contracted small-pox on steamer "Catalonia," from Liverpool. 20. Vaccinated in infancy and nine years ago. Nov. 18, 19 and 20 were contracted from No. 17. 24. Vaccinated in infancy and November 6; contracted from No. 16. 25. Vaccinated in infancy and November 6. 33. Vaccinated in infancy; two imperfect scars. 34. Vaccinated December 9; too late to take effect. 39. Vaccinated December 7.

These forty-four cases present several points which are worthy of note. Most of the cases (43 out of 44) occurred in the cities and large towns. Out of the first sixteen cases which occurred during the year, eleven occurred in places where paper mills using rags exist. There has been no serious epidemic of small-pox in the

State during the past twenty-five years in which cases have not occurred in considerable numbers in such cities and towns, and while only two of the persons in the foregoing list are reported as being employed in handling rags, several of the others are known to have lived in the same families or tenements with persons so employed.

Ten only out of the forty-four are reported as having been of American birth.

Out of the whole number 25 or 56.8 per cent. were females, a circumstance which is quite unusual since the majority of cases are commonly men.

Of the whole number, 8 were under five years of age, 6 were school-children or children of school age, eight to fourteen years, and of these, 3 were unvaccinated.

*Vaccination.*—In consequence of the unusual prevalence of small-pox during the past season it seems proper to state some of the principles relating to vaccination as clearly as possible.

The experience of nearly a century with vaccination has demonstrated its protective power beyond a reasonable doubt. This power, however, is not absolute, nor does it continue throughout adult life. Hence it is desirable that revaccination should be performed at or before the period of puberty.

The provisions of the German law afford a very good rule in this respect. It is therein required that every child shall be vaccinated before the September of the year following its birth, and that every school-child shall be re-vaccinated during its twelfth year.

The result of the enactment of this law in 1874 has been the almost complete extinction of small-pox in Germany since that date. In the six largest cities of the empire the mortality from small-pox was reduced from 92 per 100,000 of the population to 1.4 in the ten years after the enactment of the law.

The opposition to the practice of vaccination is by no means new. It is coeval with the discovery of this extremely valuable means of disease prevention, and the past century has developed nothing new on the part of its opponents, while vaccination itself has received the strongest support in the brilliant researches of Pasteur and others in the direction of protective inoculation for other diseases.

The first secretary of the State Board of Health, Dr. Derby, said of vaccination :—

We may turn the question with ingenious skill, so that its many facets shall reflect a multitude of curious lights, and after all we find that we rest in a security against this most horrid pestilence unknown to former generations.

The operation of vaccination should always be conducted with the greatest care. The following rules (modified from those of the Local Government Board of England) may be observed with advantage :—

1. In the vaccination of infants ascertain that there is not any febrile condition, or irritation of the bowels, or an unhealthy state of the skin; especially any chafing or eczema behind the ears or in the groin, or elsewhere in the folds of the skin. Where there has been recent exposure to the infection of measles or scarlet-fever, and where erysipelas prevails in the place of residence, vaccination should be delayed for a month, or until danger of other infection has passed.

2. In all ordinary cases of primary vaccination, make at least two insertions of lymph not less than a half inch apart. It is desirable that the total area of vesiculation on the same day of the week following the vaccination should amount to not less than a half of a square inch.

3. Direct that care be taken for keeping the vesicles uninjured during their progress, and for avoiding the premature removal of the crusts. Do not use any needless means of "protection" or of "dressing" to a vaccinated arm; but, if in a particular case, you find reason for means of "protection" or of "dressing," define the material and the manner of use of the appliances best adapted to the case, avoiding all such as cannot be readily destroyed and replaced whenever they become soiled.

4. Keep a careful record of vaccinations, in which may be placed the following items: date of vaccination, name, age and sex of child, character and source of lymph used, number of insertions, result of inspection at end of a week, remarks, abnormal appearances, etc.

Record as "successful" only those cases in which a normal vesicle has been produced. In cases of revaccination record as successful only those cases in which either vesicles, normal or modified, or papules surrounded by areolæ, have resulted.

5. Use bovine lymph preferably. In times of epidemics of small-pox, and especially in cases where persons about to be vaccinated have been recently exposed to small-pox, the age of the lymph (time since it was taken from the animal) should be definitely ascertained, and in such cases recent lymph should always be employed in preference to that which is more than ten days old. If bovine lymph cannot be obtained and the lymph from a healthy infant taken on the seventh day after vaccination can be had, this may be used. Humanized lymph should never be taken

from cases of revaccination, but invariably from a primary case and from an infant in good health and of healthy parentage.

6. Keep in good condition the lancets or other instruments employed for vaccination and use them for no other purpose.

When vaccinating, have a clean napkin and a glass of water containing a disinfectant at your side, with which invariably cleanse the lancet after each operation before proceeding to another. Dipping the lancet in strong alcohol and immediately passing it through the flame of a lamp undoubtedly serves to sterilize it.

Never use an ivory point a second time either for the conveyance or for the storage of lymph, but when they have been put to their proper use, break or otherwise destroy them.

“The best results, on the whole, are those which follow the plan of scarification or abrasion.” — *Seaton*.

The greatest care should be taken in performing the operation to secure aseptic conditions, in other words, absolute cleanliness. For this purpose the place of insertion, preferably the outer and anterior part of the arm from three to five inches below the bend of the shoulder, should be washed with soap and water and then wiped dry.

Scarify or lightly abrade the surface in at least two places about an inch apart, until the scarified spots appear slightly red and moist, but not enough to draw blood freely.

Moisten the ivory slips slightly at the points with pure water, and wipe off the lymph upon the scarified places, using at least two points for each person vaccinated.

Never use one point for two persons.

The after treatment: If any blood remains at the points of insertion it should be allowed to dry, and should not be washed off until the third morning after vaccination, when it may be removed by washing gently with a little pure warm water and a clean flannel or linen cloth. After this, a clean piece of soft linen may be sewed around the arm to prevent the sleeve from chafing the vesicles. This should be changed daily.

7. The vaccinator should in all cases require that each vaccinated person should appear at the end of a week for inspection, and especially in each case of primary vaccination, if the operation proves ineffectual, the vaccination should be repeated with fresh lymph.

*Cases of Doubtful Diagnosis.* — In all of the comparatively slight epidemics of small-pox which have occurred in recent years there has been a considerable number of cases in which the diagnosis, especially in the early stage of the disease, was more or less involved in doubt, and this was particularly true of those cases which occurred in the practice of young physicians who have entered upon practice since the epidemic of 1872-73.

Cases of measles, of chicken-pox, as well as some of the ordinary forms of skin diseases, have been mistaken for small-pox, while cases of genuine variola have been reported as chicken-pox, measles, etc. This fact is not to be wondered at when it is known that small-pox has been of such rare occurrence during the twenty years intervening between 1873 and 1893 that probably not one physician in a hundred in the State has met with a single case during that time.

In consequence of this fact it is desirable that any doubtful cases occurring in the practice of physicians who are not familiar with the natural history of the disease should be examined in consultation with a physician who has had experience in such cases. Much doubt and much annoyance to communities where such cases may occur may thus be avoided, and in some instances serious outbreaks may be prevented.

#### *Other Infectious Diseases.*

From such reports as have been received from local boards of health during 1893 it appears that the prevalence of diphtheria and typhoid fever has differed but little in severity from that of the previous year. The number of reported cases and deaths from each of these causes was but little greater for each disease.

From scarlet fever the reported cases and deaths were much larger in number than those of either 1891 or 1892.

From measles the cases and deaths were greater than those of 1891 and very largely in excess of those of 1892.

The statistics giving the number of reported cases and of reported deaths, together with the ratios of fatality, may be found at page 741, under the head of Health of Towns.

Many requests were received during the year for advice in regard to the management and control of infectious diseases, and visits were made to Provincetown, Newburyport, Ludlow, Somerville, Dalton, Hanover, Douglas, Falmouth, Rowley, Topsfield and other places for the purpose of investigating local outbreaks of typhoid fever, scarlet fever and diphtheria, and for affording such assistance to local boards of health as it was in the power of the State Board to give.

*Notification of Infectious Diseases.*

Among the different measures employed by sanitary authorities for the prevention of the spread of infectious diseases, the notification of the occurrence of such diseases now occupies a prominent place. Municipal authorities especially should have the requisite power everywhere to require immediate notice to be given them of every fresh outbreak of diseases dangerous to the public health in order that such authorities may take proper measures for the protection of the community.

The chief advantages of a system of notification lie in the possibility which is thus given to a local board of health to determine the extent of prevalence of an epidemic or a localized outbreak, and to inquire into the local causes which have operated to produce it. The board can then act intelligently in applying the proper remedies for preventing its further spread.

Laws enacted with this object in view have been in force in the older States for many years, but not until within the past ten or twenty years have pains been taken to execute such statutes with such degree of efficiency as to make them really protective. The law requiring the householder to report each case of dangerous disease to the local authority was enacted in Massachusetts in 1792, and that which requires the same duty on the part of the attending physician was enacted in 1827.

There can be no doubt that the law relative to notification has been productive of excellent results in the prevention of disease, especially in the cities and large towns. It has furnished the local boards of health with the necessary information relative to the origin of outbreaks of infectious disease, and in many instances enabled them to take timely steps for preventing its further spread. The law of 1884 requiring local boards to keep records upon this important matter has furnished information as to the prevalence of certain diseases in the principal cities and towns of the State, and has enabled school authorities to guard against the introduction and spread of contagious diseases in the public schools by means of the provision which requires the local board of health to notify the school committee of the occurrence of all cases of such contagious disease. In the smaller towns it is probable that instances of failure to comply with the provisions of the statute are much more frequent than they are in cities.

The statutes referred to in the foregoing comments are as follows:—

[PUBLIC STATUTES, CHAPTER 80, SECTION 78; ACTS OF 1884, CHAPTER 98, AND ACTS OF 1891, CHAPTER 188.]

(1.) When a householder knows that a person within his family is sick of small-pox, diphtheria, scarlet fever or any other disease dangerous to the public health, he shall immediately give notice thereof to the selectmen or board of health of the town in which he dwells, and upon the death, recovery or removal of such person, the rooms occupied and the articles used by him shall be disinfected by such householder in a manner approved by the board of health. Any person neglecting or refusing to comply with either of the above provisions shall forfeit a sum not exceeding one hundred dollars.

(2.) When a physician knows that a person whom he is called to visit is infected with small-pox, diphtheria, scarlet fever or any other disease dangerous to public health, he shall immediately give notice thereof in writing, over his own signature, to the selectmen or board of health of the town; and if he refuses or neglects to give such notice he shall forfeit for each offence not less than fifty nor more than two hundred dollars.

(3.) The boards of health in the several cities and towns shall cause a record to be kept of all reports received in pursuance of the preceding sections, and such record shall contain the names of all persons who are sick, the localities in which they live, the diseases with which they are affected, together with the date and the names of the persons reporting any such cases. The boards of health shall give the school committee immediate information of all cases of contagious diseases reported to them according to the provisions of this act.

(4.) The secretary of the Commonwealth shall furnish the boards of health with blank books for the record of cases of contagious diseases as above provided.

As an additional measure in the same direction the Legislature of 1893 enacted the following law, requiring that contagious diseases reported to the local boards of health shall, in turn, be reported by them to the State Board of Health:—

[CHAPTER 302 OF THE ACTS OF 1893.]

(1.) When the board of health of any city or town has had notice of the occurrence of a case of small-pox or any other disease dangerous to the public health in such city or town, such board of health shall, within twenty-four hours after the receipt of such notice, notify the State Board of Health of the same.

(2.) If the board of health of the city or town, in which a case of small-pox or any other disease dangerous to the public health has occurred,

refuses or neglects to send a notice as required in section one, such city or town shall forfeit its claim upon the Commonwealth for the payment of any expenses which may be incurred as provided in section eighty-three of chapter eighty of the Public Statutes.

This recent law went into effect in June, 1893, but very few returns in compliance with its provisions were received by the State Board of Health until after public notice had been given by the Board by means of a circular which was distributed to every Board of Health throughout the State.

As the "diseases dangerous to the public health" were not specified in the foregoing act, with the exception of small-pox, the Board deemed it desirable for the sake of securing uniform action on the part of local boards, that some definite expression of opinion should be made as to the meaning of the term "other diseases dangerous to the public health."

Hence, in the circular named above, the Board suggested that, in addition to *small-pox*, the following diseases shall be considered as dangerous to the public health within the meaning of the foregoing act: *scarlet fever, measles, typhoid fever, diphtheria, membranous croup, cholera, yellow fever, typhus fever, cerebro-spinal meningitis, hydrophobia, malignant pustule, leprosy and trichinosis.*

A supply of postal blanks was forwarded with the circular for the purpose of enabling local boards of health to comply with the terms of the act.

Various attempts have been made in England to enact a similar statute, but these efforts were unsuccessful until 1889. By the terms of the law then enacted the notification of infectious diseases to the sanitary authority was made compulsory throughout London, while the principle of local option was applied to all other districts.

During the year in which this bill was under consideration by Parliament, intense opposition had been manifested by many of the members of the medical profession throughout England. Objections were offered not only by the people, but also by the medical profession, but the bill passed and finally became a law.

The fallacy of the objections has been abundantly proven by the three years' experience of the towns of England where the Notification Act has been adopted. The notification of each case is made by a certificate furnished by the attending physician, for which a fee of two shillings and sixpence is paid, except in a case where the person

giving the certificate is the medical officer of a public institution, when the fee is one shilling.

The diseases to which this act applies are small-pox, cholera, diphtheria, membranous croup, erysipelas, scarlet-fever, typhus, typhoid and puerperal fevers, and any other infectious disease which may be added to this list by the sanitary authority of a district.

Up to the year 1892, the act had been adopted in 1,051 districts, having an aggregate population of nearly sixteen millions, to which should be added the population of London and fifty towns in which local acts made it compulsory, making in all a population of 24,012,399 over which the act was in force, out of a total of 29,001,018. In a few towns the sanitary authorities had availed themselves of the power to require notification in the case of measles, r  theln, chicken-pox and hydrophobia.

Further information as to the details of the operation of the statute of 1893 may be found upon page 639.

#### OFFENSIVE TRADES.

Under the provisions of the acts relating to noxious and offensive trades the State Board of Health is authorized to hear parties making complaints, and when "in the judgment of the Board the public health or the public comfort and convenience require, the Board may order any person to desist and cease from further carrying on said trades or occupations." No applications under this act were received during the year, but visits and inspections were made at the request of local boards of health in two instances, where rendering works were being conducted.

#### THE BOARD'S EXHIBIT AT THE COLUMBIAN EXPOSITION (1893).

The subject of public hygiene was represented at the Columbian Exposition at Chicago by exhibitions of the work of State and local boards of health. The exhibits of this important department of public work were installed in the Anthropological Building, in the south part of Jackson Park. Of these exhibits none created greater or more favorable comment than that of the State Board of Health of Massachusetts.

It is proper that some account of the exhibition should be made a matter of public record in this report of work for the year 1893.

A communication was received Sept. 24, 1892, from the superintendent of the Bureau of Hygiene and Sanitation of the Department

of Liberal Arts of the Columbian Exposition, calling the attention of the Board to the opportunity that would be given at the Fair for placing before the public the work of State boards of health in the prevention of infectious diseases, and at the same time asking whether the Board desired to be represented at the Exposition.

At a later date (Dec. 28, 1892) further information was received upon the subject, together with a blank form of application for allotment of space in which to install the exhibit of the Board.

At the next meeting of the Board (January, 1893) it was voted to ask for 1,200 square feet of space for the Board's exhibit.

The Board was informed that, in consequence of the fact that only 10,000 feet could be devoted to the whole subject of hygiene and sanitation in the United States, it would be impossible to afford an eighth of it to the State of Massachusetts. It was therefore finally decided to grant the Board 500 feet of space for its purpose. To this space were ultimately added 120 square feet.

An appropriation had already been provided by the Legislature to defray the expenses of such representations as might be made at the Exposition by different departments of the State government, and the sum of \$4,000 was set aside for the exhibit of the State Board of Health. The Board then directed that an exhibit should be prepared representing the progress of public hygiene in the State.

The exhibit consisted of the following items:—

*General Sanitary Work of the Board.*

Complete set of reports of State Board of Health from 1869 to 1891.

Special reports of the Board, circulars upon infectious diseases and other health topics, sets of blank forms and manual of health laws.

Reports of city boards of health of Massachusetts for the year 1892.

*Charts and Diagrams illustrating the Following Subjects.*

The death-rate of Massachusetts for a series of years.

Effect of density of population on the general death rate.

Effect of density of population on the death rate from each of the following diseases (for twenty years, 1871–90): Measles, scarlet fever, diphtheria, small-pox, typhoid fever, cholera infantum, consumption and pneumonia.

Improvement in registration.

Decline in death rates from certain causes.

Seasonal mortality in Massachusetts.

*Geographical Distribution of Eight Diseases.*

Eight maps showing the comparative mortality from measles, scarlet fever, diphtheria, small-pox, typhoid fever, cholera infantum, phthisis and pneumonia.

Diagrams and maps illustrating epidemics of typhoid fever in Springfield and Lowell.

*Engineering Department ( Water Supply and Sewerage ).*

Model of Lawrence Experiment Station, carefully constructed of wood and iron painted, and in a scale of one-half inch to the foot.

Sand sieve.

Steam sterilizer.

Thermostat.

Galvanized-iron filter.

Complete battery of stills.

Sections of sand filters, in glass tubes.

Apparatus for determining the color of waters.

Bacteria stand, with tubes.

Sets of double dishes.

Large map of Massachusetts showing the normal chlorine of different regions.

Small map of Massachusetts showing the normal chlorine of different regions.

Water-shed map of Massachusetts.

Lower basin of Merrimack River (blue print).

Temperature chart.

Chart showing advice to cities and towns, water supplies.

Chart showing advice to cities and towns, sewage disposal.

Chart showing average of water analyses.

Map of North Metropolitan Sewerage System.

Map of Lawrence city filter.

Photographs of Framingham sewage beds.

Pumping station.

Applying sewage. (2 photographs.)

Cornfield treated with sewage.

Photographs of Marlborough sewage beds.

Gate-house.

Underdrains.

Filter-bed.

Filter-beds after harrowing.

Room 86, Massachusetts Institute of Technology (Laboratory of State Board of Health). (2 photographs.)

Lawrence Experiment Station. (3 photographs.)

Photographs of bacteria cultures.

City water of Lawrence and Tank 8.

Tanks 1, 2, 6 and 13.

Forty one-gallon bottles, containing:—

Samples of sewage applied to each of the filters at Lawrence, Framingham, etc.

Samples of effluents from sewage-filters at Lawrence, Framingham, etc.

Samples of sewage containing dyes (with water before and after filtration).

Samples of Merrimack River water before and after filtration.

Samples of surface and ground waters from rivers, ponds, reservoirs, wells, springs, etc. (pure and polluted).

Series of eight-ounce bottles containing samples of filtering materials, sand, gravel, etc.

*Department of Food and Drug Inspection.*

Charts showing ratio of adulteration of milk in Massachusetts.

Charts showing ratio of adulteration of other kinds of food.

Charts showing ratio of adulteration of spices.

Chart showing decrease in ratio of hogs infected with trichinæ under improved modes of feeding.

Chart showing ratio of expenditure for food, clothing, rent, fuel, etc., in different countries.

Micro-photographs of pure articles of food: coffee, pepper, mustard, cloves, ginger, etc.

Micro-photographs of the same when adulterated.

Samples of pure foods, in glass bottles.

Samples of adulterants used in the foregoing, as sold commercially for the purpose of adulteration.

Models of trichinæ, free (male and female) and encysted.

Information was received that the Anthropological Building would be ready for the reception of exhibits by the 12th of April.

The material was collected at the building of the Mechanics' Charitable Association in Boston, and was boxed, ready for shipment, in fifty-four packages, and left Boston on April 10. It arrived at the Fair grounds in good condition on April 12, but the building was then in no condition to receive it, and it was therefore stored near by until the building could be completed. The roof was not put on till April 29.

Prof. W. T. Sedgwick was given charge of installing the exhibit, and went to Chicago for that purpose. He obtained the services of attendants, so that some one was in charge of the exhibit from the outset to the close of the Exposition, a fact which contributed very largely to its success.

In commenting upon this exhibit, Mr. E. C. Hovey, secretary and executive officer of the Massachusetts commission at the Fair, says :—

Two exhibits alone were well-nigh worth the entire sum expended by the Commonwealth on her contributions to these important departments. The exhibits of the Massachusetts State Board of Health and the Rumford Kitchen were *sui generis*, and told to the world in a most striking manner their story of patient investigation and continued research. Through the auspices of the State Board of Health there was installed an exhibit which, in a most complete and graphic manner, laid before the visitor the work which has been accomplished in the State in dealing with the problems of health as dependent upon sanitation. Here also was to be seen a model of the Experiment Station in Lawrence, which it may be truly said has not its equal in the country. The important investigations made by the Board of Health, looking to the prevention of the adulteration of food, were effectively shown, and the walls were covered with charts and statistics which served to demonstrate the nature of the researches made by the Board, researches which have had, and will continue to have, marked influence on the health of the citizens of the Commonwealth.\*

Many thousands of visitors viewed the exhibit of the Board during the continuance of the Fair, and especially during the week of the congress of public hygiene. The Board published a large edition of a guide or prospectus of the exhibit, which was distributed free to all visitors. The exhibit also received very favorable comment in the various medical and sanitary periodicals, not only in the United States but also in foreign countries.

The following notice of award has been received by the Board :—

#### UNITED STATES.

##### DEPARTMENT OF LIBERAL ARTS.

*Exhibitor.* — State Board of Health. *Group 147.* — Class 833.

*Address.* — Boston, Mass. *Exhibit.* — Maps, Charts and Models.

#### AWARD.

For exhaustive examinations and reports upon the public water supplies of the State ; the relation of water supply to the public health, resulting in a definite knowledge as to the ways in which certain diseases are disseminated ; and the best methods of protecting the purity of waters used for

---

\* New England Magazine, February, 1894. Article by Commissioner E. C. Hovey.

tuberculous patient should be disinfected and especially the floor and lower parts of the walls. For this purpose washing the floor and all woodwork with a corrosive sublimate solution, one part to one thousand (about one teaspoonful to a gallon of water) should be practised, and the bed and clothing of the last occupant should be submitted to steam disinfection or to boiling water. Strong soapsuds also have efficient disinfecting power, and may be used for washing floors and woodwork. The disinfection should be thoroughly done, but especially so in cases where the habits of the consumptive in regard to disposal of his sputa have been careless.

As a means of spreading information upon this important subject, local boards of health can undoubtedly accomplish much toward the prevention of consumption, by issuing a circular like the following: —

*The Prevention of Consumption.*

Consumption is the most destructive disease of New England, the number of persons dying annually from this cause in Massachusetts amounting to nearly six thousand.

The disease is infectious, and can be communicated from one person to another. The chief danger exists in the expectoration of the sick, and if this expectoration is carefully destroyed little danger need be feared.

Consumptives should be instructed not to spit upon the floors of rooms, public halls, street and railway cars, and other vehicles, nor in the streets, but into pieces of cloth, or receptacles made for the purpose, containing water, or a saturated solution of carbolic acid (one part of carbolic acid crystals to about fifteen parts of water). Such bits of cloth should be destroyed by fire, before the sputa become dry, and other receptacles should be cleansed with scalding water, their contents having been destroyed or otherwise carefully disposed of. Handkerchiefs which may have been used from necessity should be boiled half an hour before washing.

A healthy person should not sleep in the same room with a consumptive.

Remember that sputa must never be allowed to become dry.

OFFICE OF THE STATE BOARD OF HEALTH, BOSTON.  
January, 1896.

LOCAL BOARDS OF HEALTH.

Nearly fifty years ago (1850) the sanitary commission of Massachusetts advised the obligatory appointment of boards of health in every city and town in the State, and after the establishment of the State Board of Health in 1869 this Board frequently called attention to the need of legislation having this end in view. But not until 1877 was legislation enacted requiring such boards to be appointed as a compulsory measure, and even then the requirement applied to cities only. The Board has from time to time urged the necessity of further legislation requiring similar action on the part of towns, and especially in the case of those having large populations.

the Public Statutes (edition of 1882) but also of each of the Blue Books containing the acts and resolves of each successive year since 1882. Copies of the Manual have been furnished to each of the local boards of health throughout the State, to the public health committee of the Legislature, and to other persons interested in public hygiene. The book contains about 200 pages, with a very full index. It has the laws relating to the public health, including those which pertain to the inspection of food and drugs, the registration of vital statistics and the medical examiners' laws.

#### CREMATION.

Under the provisions of chapter 265 of the Acts of 1885 the Legislature authorized the formation of corporations for the purpose of incinerating the bodies of the dead.

By the terms of this act it was provided that —

Every such corporation may acquire by gift, devise or purchase, and hold in fee simple so much real estate not exceeding in value fifty thousand dollars as may be necessary for carrying out the objects connected with and appropriate to the purposes of said corporation, and situated in such place as the state board of health may determine to be suitable for said objects and purposes. No building shall be erected, occupied or used by such corporation until the location and plans thereof, with all details of construction, have been submitted to and approved by said board or some person designated by it to examine them.

Every such corporation may make by-laws and regulations consistent with law and subject to the approval of said state board, for the reception and cremation of bodies of deceased persons, and for the disposition of the ashes remaining therefrom.

Further provision was made in the same act to prevent the concealment of crime in the case of cremated bodies.

Acting under the provisions of this act the Massachusetts Cremation Society applied to the Board April 3, 1893, requesting its approval of a location for a crematory in the city of Boston, the location being a tract of nearly two acres on the north-west side of Walk Hill Street, near the Forest Hills Cemetery.

The Board, after viewing the premises, approved the location. Subsequently, the plans and method of cremation were submitted to the Board, and after examination by a competent engineer these also were approved, together with certain regulations adopted by

topics relative to the work of municipal boards have been presented for discussion. Committees have been appointed to confer with legislative health committees with reference to matters of importance which appear to require further legislation.

The association publishes a quarterly journal in which its transactions appear.

#### OFFENSIVE TRADES.

No complaints were made to the Board during the year under the provisions of the acts relating to offensive trades, and consequently no hearings were held. The board of health of Newburyport requested the advice of the State Board in regard to a rendering establishment in that city, situated at some distance from the populous part of the city. The secretary conferred with the secretary of the local board, and on visiting the establishment in question found it in an extremely filthy condition, both internally and externally, some thirty or forty carcasses of horses in different stages of decomposition lying unburied upon the surface of the ground, while many others, insufficiently buried, had been uncovered by dogs.

Information was received that the premises were subsequently put in good condition and that no further complaints had been made in relation to the same.

#### LOCAL NUISANCES.

A very considerable part of the correspondence received by the Board consists of letters from individuals, or of petitions signed by greater or less numbers of citizens, requesting the State Board to abate local nuisances existing in cities and towns. Often such letters or petitions call the attention of the State Board to the fact that the local board of health has been requested to abate the nuisance but has either refused or neglected to attend to the matter.

So frequent has this class of correspondence become that the State Board has issued a circular which is used as a reply to letters of this character, calling attention to the fact that the State Board has no power or authority to abate an ordinary local nuisance, but that ample power is conferred upon the local board of health to take all proper measures in such cases. If the local board of health refuses or neglects to comply with the request of the petitioners, then the matter may be referred to the county commissioners under the provisions of chapter 80, sections 36, 37 and 38, but not to the State Board of Health.

This statute, however, does not prevent the State Board from consulting with and advising local boards in regard to the disposal of local nuisances whenever such action is necessary.

#### STATISTICAL SUMMARIES OF DISEASE AND MORTALITY.

These summaries comprise the results of the collection of such statistics as are furnished to the Board by the local authorities of cities and towns, either voluntarily or by statute requirements. They consist of four different series or sets of tabular material, as follows:—

1. The weekly mortality returns, or the summary of the voluntary returns of deaths in those cities and towns whose registration officials return these data to the State Board.

2. Summary of cases of infectious diseases reported to local boards of health, selected and compiled from the annual reports of such boards.

3. Summary of cases of infectious diseases reported by local boards to the State Board—chiefly diphtheria, scarlet-fever, measles and typhoid fever—under statutory requirement.

4. Annual returns of deaths in each city and town having over 5,000 population, also by statutory requirement.

As a matter of convenience these summaries have been grouped together, and are presented on pages 711–750 of this report.

#### NOTIFICATION OF INFECTIOUS DISEASES.

The plan of requiring notice to be given of the occurrence of infectious diseases was established nearly a century ago by statutes making such notices compulsory, both on the part of the householder and of the attending physician. But little care was taken to secure the enforcement of such laws until within the past twenty-five years, when these laws were made more efficient by the requirement of penalties for neglect to comply with them and the introduction of other features providing for the systematic recording of data by local boards of health, and still later, by the statute requiring a further report by the local board to the State Board of Health. Similar statutes have been in force in England for several years, and the information thus furnished has frequently proved of great value in tracing the cause of epidemics and of devising and providing means for their prevention.

A summary of the reports received from the different municipal authorities required to report to the State Board of Health may be found in that portion of the report entitled Statistical Summaries of Disease and Mortality.

## REGISTRATION OF VITAL STATISTICS.

In the following summary of the vital statistics of the State for the year 1892, the estimate of population employed as a basis is made upon the same plan as that of the previous year, namely, the geometric rate of increase. Upon this basis the estimate of population for the year 1892 is 2,369,993.

There were 22,507 marriages, 65,824 living births, 2,293 stillbirths and 48,762 deaths registered in Massachusetts in 1892.

The ratios to the estimated living population were as follows : —

|                                       |           |       |                                     |
|---------------------------------------|-----------|-------|-------------------------------------|
| Marriage rate,                        | . . . . . | 9.50  | per 1,000 of the living population. |
| Persons married,                      | . . . . . | 18.99 | " " " " "                           |
| Birth rate,                           | . . . . . | 27.77 | " " " " "                           |
| Death rate,                           | . . . . . | 20.57 | " " " " "                           |
| Excess of birth rate over death rate, | . . . . . | 7.20  | " " " " "                           |

*International Vital Statistics.*

In the following summary are presented the marriage, birth and death rates of the six New England States and those of the principal countries of Europe having registration for a period of twenty years (1871–90) and for the years 1891 and 1892. The first year of registration of Maine completes the list of the New England States for the year 1892.

The six New England States embrace a population of about five millions, and the entire population of the countries embraced in this summary numbers about two hundred and twenty-five millions.

*Summary of the Vital Statistics of the Principal Countries of Europe for Twenty Years, and for 1891 and 1892, together with those of the New England States.*

| STATES AND COUNTRIES.        | TWENTY YEARS — 1871-1890. |             |             |                                       | 1891.          |             |             |                                       | 1892.          |             |             |                                       |

\* Seven years. Registration of births said to be defective.

† Fifteen years.

‡ Nineteen years.

§ Excess of death rate.

*Marriages.*

The number of marriages (22,507) was greater than that of any previous year. The greatest number occurred in November (2,716) and the least number in March (1,037).

The marriage rate was 18.99, and was higher than that of any year since 1887, when it was 19.0. The estimated marriage rate of the decennial period ending with 1892 was 18.61.

*Births.*

The number of living births registered in Massachusetts during the year 1892 was 65,824, and the birth rate, as calculated upon an estimated population of 2,369,993, was 27.77 per 1,000 of the living population. This was the highest birth rate of any year since 1874, when it was 28.32. The lowest birth rate in the intervening period was that of 1879, which was 22.94. The estimated birth rate of the decennial period ending with 1892 was 26.08.

The ratio of males to females among living births where the sex was stated was 105.6 females to each 100 males.

The greatest number of births occurred in December and the least number in February.

There were 990 illegitimate births registered, or 15 per 1,000 of the living births registered during the year, as compared with 1,078, or 17.1 per 1,000 in 1891.

The births in the thirty cities were 46,597, as compared with 43,828 in 1891, an increase of 6.3 per cent. Those in the remainder of the State were 19,227, as compared with 19,176 in 1891, an increase of less than three-tenths of 1 per cent.

*Deaths.*

The number of deaths (48,762) was greater than that of any previous year. The death rate (20.57 per 1,000) was higher than that of any previous year since 1875. The estimated death rate of the decennial period ending with 1892 was 19.64.

*Infant Mortality.* — The number of deaths of infants under one year old was 10,649, or 21.84 of the total mortality, which was less than that of either 1891 or 1890, and was also greater than the mean of the twenty-year period (1873–92).

The deaths of children under five were 15,225, or 31.22 per cent. of the total mortality, which was less than that of any year for the

past twenty years except that of 1882, which was nearly identical with it.

As compared with the births, the mortality of infants under one was 16.18 per cent. of the living births, which was slightly greater than that of 1891, and also greater than the mean of the twenty-year period (1873-92).

The deaths of centenarians reported in 1892 were thirteen in number, nine of whom were women, and ten were of foreign birth. Of the three women who were of native birth, one died in her native town, and each of the others in a town adjoining her native town.

*Sex.* — The deaths of males were 24,643 and those of females 24,119. But, by the census of 1890, the females were largely in excess of the males, in the ratio of 51.42 per cent. of the former to 48.58 of the latter (nearly). If the same ratio prevailed in 1892, the death rate of males was 21.40 per 1,000, and that of females 19.79, these ratios being in each case higher than those of the census year 1890, and also higher than the mean of the seven census years, 1860, '65, '70, '75, '80, '85, '90.

Stating this more clearly, the deaths of males to 1,000 deaths of females in equal numbers living were 1,059 in 1890, while in 1892, the difference in population of the two sexes being estimated in the same ratio, the deaths of males to 1,000 females in equal numbers living were 1,081. In England, for 1891, the deaths of males to 1,000 deaths of females were 1,128, and for the ten-year period (1881-90) they were 1,123.

### *Causes of Death.*

The number of deaths, the causes of which were not registered in 1892, was 470, or .96 of 1 per cent. of the mortality from all causes. This ratio was smaller than that of any previous year since the beginning of registration, except that of 1891, which was .9 of 1 per cent.

The average of the ten years ending with 1892 was 1.23 per cent. of the total mortality of the period.

The sanitary significance of a table in which is presented the ratio of deaths from specified causes, or groups of causes, to the living population, must be acknowledged, as compared with the older method of comparison with the total mortality. Hence the following table is introduced, in which are presented the deaths from each group of causes, together with the rate per million living for each

group for 1892, and the rate per million for each year of the period (1883-92).

The practical value of international vital statistics becomes more apparent every year. An impetus has been given to such work by the labors of the International Statistical Institute, which convened at Chicago in 1893.

For the sake of comparison the column of means for the ten-year period (1881-90) for England has been added to the following table from the Fifty-fourth Report of the Registrar General of England for 1891.

The deaths from the group of infectious diseases in Massachusetts in 1892 were greater than the mean for the ten-year period (1883-92).

The deaths from the group of constitutional diseases in 1892 were less than those of the ten-year period.

The deaths from the developmental group of causes were slightly less than those of the decade.

The deaths from local diseases have increased from a rate of 7,572 per million in 1884 to 9,651 per million in 1892. The mean ratio for the period was 8,496.

The deaths from violence have not varied very greatly, the extremes being 894 per million in 1883, and 748 in 1884, while the mean was 815.

The deaths from ill-defined and unspecified causes have generally diminished from a maximum of 357 per million in 1883 to a minimum of 176 in 1891, the mean being 242.

The lower line may be read as a general death rate per million, or per thousand of the population, as convenience may dictate, in the latter case the comma being used as a decimal point.

| 1889, | 3,440      | 15.8                          | 8.23                           | 310            | 1.4                           | .74                            | 1,325   | 6.1                           | 3.17                           | 1,298            | 5.8                           | 3.01                           | 3,280           | 14.2                          | 7.85                           | 4,313           | 19.8                          | 10.32                          |
| 1890, | 4,038      | 18.0                          | 9.28                           | 363            | 1.6                           | .83                            | 1,387   | 6.2                           | 3.19                           | 1,273            | 5.7                           | 2.92                           | 3,417           | 15.3                          | 7.85                           | 4,580           | 19.6                          | 10.08                          |
| 1891, | 4,337      | 18.8                          | 9.60                           | 219            | .9                            | .48                            | 1,395   | 6.1                           | 3.09                           | 1,474            | 6.4                           | 3.26                           | 3,592           | 15.6                          | 7.95                           | 4,711           | 20.5                          | 10.42                          |
| 1892, | 5,020      | 21.2                          | 10.29                          | 248            | 1.0                           | .51                            | 1,402   | 6.9                           | 2.87                           | 1,635            | 6.6                           | 3.15                           | 3,783           | 18.7                          | 7.65                           | 5,036           | 21.2                          | 10.33                          |

In the last two tables are presented the numbers of deaths, the death rates per 10,000 of the living population and the percentage of the total mortality for each of the twenty years ending with 1892 and for each of thirteen prominent causes and groups of causes of death.

*Small-pox.* — The number of deaths from small-pox during the year was 2, as compared with 1 in 1891, 1 in 1890, 4 in 1889 and 8 in 1888.

Compared with the estimated living population the death rate from this cause was only .01 of 1 per 10,000 and the percentage of the total mortality was only .004 of 1 per cent. (Further information relative to the prevalence of small-pox will be found under the head of infectious diseases, page viii.)

*Measles.* — The number of deaths from measles in 1892 was 88, as compared with 236 in 1891 and 114 in 1890. The death rate per 10,000 of the estimated population from this cause was .4 and the percentage of the total mortality was .18.

The number of deaths from this cause was less than that of any year since 1884, when it was 75. The minimum death rate from this cause for the twenty-year period was .1 per 10,000 in 1879, and the maximum was 2.2 in 1887.

*Scarlet Fever.* — The number of deaths from scarlet fever in 1892 was 669, as compared with 246 in 1891 and 196 in 1890 and was the greatest number in any year since 1879.

The death rate per 10,000 of the estimated population from this cause was 2.8 and the percentage of the total mortality 1.37.

The minimum death rate from this cause for the twenty-year period (1873-92) was .8 per 10,000 in 1889, and the maximum was 10.2 in 1875.

*Diphtheria and Croup.* — The number of deaths from diphtheria and croup in 1892 was 1,455 as compared with 1,218 in 1891 and 1,626 in 1890.

The death rate per 10,000 of the estimated living population was 6.1 and the percentage of the total mortality was 2.98.

The minimum death rate from these causes for the twenty-year period ending with 1892 was 4.7 per 10,000 in 1873, and the maximum was 19.6 in 1876.

The mean death rate from these causes for the first half of the twenty-year period was much greater than that of the last half.

*Typhoid Fever.* — The number of deaths from this cause in 1892 was 827, as compared with 821 in 1891 and 835 in 1890.

The death rate from this cause per 10,000 of the estimated population was 3.5 and the percentage of the total mortality was 1.69.

The minimum death rate for the twenty-year period ending with 1892 was 3.5 per 10,000 in 1892, and the maximum was 8.9 in 1873.

The mean death rate from this cause for the first half of the twenty-year period was considerably greater than that of the last half.

*Cholera Infantum.* — The number of deaths from cholera infantum in 1892 was 2,898, as compared with 2,771 in 1891 and 2,491 in 1890.

The death rate from this cause per 10,000 of the population was 12.2 and the percentage of the total mortality was 5.94.

The minimum death rate from cholera infantum in the twenty-year period was 7.7 per 10,000 of the estimated population in 1879, and the maximum was 16.2 in 1873, the first year of the period. In the previous year (1872) however, the death rate from this cause was higher than that of any year of registration either before or since that date.

*Consumption.* — The number of deaths from this disease in 1892 was 5,739, as compared with 5,484 in 1891 and 5,791 in 1890.

The death rate per 10,000 of the estimated population from this cause was 24.2 and the percentage of the total mortality 11.77.

The minimum death rate from this cause for the twenty-year period ending with 1892 was 23.8 per 10,000 in 1891, and the maximum was 35.3 in 1873, the first year of the period.

In comparing the two ten-year periods 1873–82 and 1883–92, there is found to be a very marked decrease in the mean death rate of the latter as compared with that of the former.

*Pneumonia.* — The deaths from pneumonia were 5,020, as compared with 4,337 in 1891 and 4,038 in 1890.

The death rate from this cause per 10,000 of the estimated population was 21.2 and the percentage of the total mortality 10.29.

The minimum death rate from pneumonia for the twenty-year period (1873–92) was 11.6 per 10,000 in 1877 and the maximum was 21.2. The increase in the death rate from pneumonia during the twenty-year period was greater than the decrease in the death rate from consumption.

*Whooping-cough.* — The deaths from whooping-cough in 1892 were 248, as compared with 219 in 1891 and 363 in 1890.

The death rate per 10,000 of the estimated population from this cause was 1 and the percentage of the total mortality was .51 of 1 per cent.

The minimum death rate of the twenty-year period ending with 1892 was .7 per 10,000 in 1883 and the maximum was 2.8 in 1874.

*Cancer.* — The deaths from cancer in 1892 were 1,402, as compared with 1,395 in 1891 and 1,387 in 1890.

The death rate from this cause per 10,000 of the living population was 5.9 in 1892 and the percentage of the total mortality was 2.87.

The minimum death rate from this cause for the twenty-year period was 3.5 per 10,000 in 1875, and the maximum was 6.2 in 1890.

There was a comparatively steady increase in the death rate from cancer from 1877 to 1890 and then a slight decrease in the last three years of the period.

*Kidney Diseases.* — The number of deaths from kidney diseases in 1892 was 1,535, as compared with 1,474 in 1891 and 1,273 in 1890.

The death rate per 10,000 of the estimated population from this group of causes in 1892 was 6.5 and the percentage of the total mortality was 3.15.

There was an increase with considerable regularity in the mortality from this cause during the twenty-year period, from a minimum of 2.9 per 10,000 of the population in 1873 to the maximum of 6.5 per 10,000 in 1892. This excessive increase is, however, more apparent than real, and may be interpreted as mainly due to more intelligent methods of diagnosis.

*Heart Diseases.* — The number of deaths from heart diseases registered in 1892 was 3,733, as compared with 3,592 in 1891 and 3,417 in 1890.

The death rate per 10,000 of the estimated population from this group of causes was 15.7 and the percentage of the total mortality was 7.65.

There has been a tolerably uniform increase in the death rate from this group of causes during the twenty-year period, the minimum death rate being 7.9 per 10,000 in 1873, '74 and '77 and the maximum 15.7 in 1892.

*Brain Diseases.* — This group includes the deaths attributed to apoplexy, paralysis, insanity, the indefinite term “cephalitis,” softening of the brain and other unspecified diseases of the brain, the whole number of deaths from this group in 1892 being 5,036 as compared with 4,711 in 1891 and 4,389 in 1890.

The death rate per 10,000 of the estimated population from these causes in 1892 was 21.2 and the percentage of the total mortality was 10.33.

The minimum death rate from this cause for the twenty-year period was 13.5 in 1877, and the maximum was 21.4 in 1888. The mean death rate from these causes in the last half of the period was considerably greater than that of the first half. For the last eight years of the period the death rate from these causes was nearly stationary.

The deaths from local diseases in Massachusetts have not differed very greatly in their relative incidence upon the population, from those of England, as is shown in the following quotation from the Registrar General's Fifty-fourth Annual Report for 1891.

“*Local Diseases.* — The most noticeable feature presented by the diseases included in this class was the great increase of mortality from diseases of the Circulatory and Respiratory Systems. The rates respectively were 1,826 and 4,474 per million living, and in each case the highest on record. The explanation is doubtless to be found in the prevalence of epidemic influenza. The deaths from nervous diseases, however, showed no such increase. They were in the proportion of 1,748 to a million living; and this rate differed but little from those of the three next preceding years. The mortality from diseases of the Urinary System was 467 per million living, this being the highest rate yet recorded, and marking a further step in the almost continuous increase shown for a long series of years under this heading.”

---

From certain infectious causes not mentioned in the foregoing enumeration there were the following numbers of deaths in 1892; those of 1891 are also presented, for the purpose of comparison: —

|                              | NUMBER OF DEATHS. |       |                            | NUMBER OF DEATHS. |       |
|------------------------------|-------------------|-------|----------------------------|-------------------|-------|
|                              | 1891.             | 1892. |                            | 1891.             | 1892. |
| Cerebro-spinal meningitis, . | 154               | 86    | Diarrhœa, . . . .          | 639               | 584   |
| Erysipelas, . . . .          | 210               | 234   | Malarial fevers, . . . .   | 62                | 81    |
| Puerperal fever, . . . .     | 56                | 81    | Hydrophobia, . . . .       | 9                 | 1     |
| Influenza, . . . .           | 546               | 967   | Glanders, . . . .          | 1                 | 0     |
| Dysentery, . . . .           | 234               | 193   | Malignant pustule, . . . . | 1                 | 5     |

*Malarial Fevers.* — There were in all 81 deaths registered in 1892 from ague and remittent fevers. These occurred as follows: —

|                           |    |                           |    |
|---------------------------|----|---------------------------|----|
| Worcester County, . . . . | 16 | Berkshire County, . . . . | 3  |
| Hampden " . . . .         | 15 | Dukes " . . . .           | 1  |
| Middlesex " . . . .       | 10 | Franklin " . . . .        | 1  |
| Suffolk " . . . .         | 9  | Plymouth " . . . .        | 1  |
| Bristol " . . . .         | 8  | Barnstable " . . . .      | 0  |
| Essex " . . . .           | 6  | Nantucket " . . . .       | 0  |
| Hampshire " . . . .       | 6  |                           |    |
| Norfolk, " . . . .        | 5  | Total, . . . .            | 81 |

The number of registered deaths from the same causes in 1891 was 62, and in 1890 60, and the total number for the ten years ending with 1892 was 584.

*Influenza.* — For the purpose of comparison the statistics relating to influenza which were published in the last report (p. xxxiv.) and also in the Forty-ninth Registration Report, 1890, are here reproduced together with those of 1892.

The deaths from certain diseases of the respiratory organs and from heart diseases are also given in the same table.

*Mortality from All Causes, and from Influenza, Pneumonia, Phthisis, Bronchitis and Heart Diseases, by Months, for 1889, 1890, 1891 and 1892.*

## 1889.

| Cause.            | January. | February. | March. | April. | May.  | June. | July. | August. | September. | October. | November. | December. | Totals. |
|-------------------|----------|-----------|--------|--------|-------|-------|-------|---------|------------|----------|-----------|-----------|---------|
| Influenza, .      | 2        | 2         | 3      | 3      | 1     | 1     | 1     | -       | -          | 2        | -         | 12        | 27      |
| Pneumonia, .      | 394      | 359       | 463    | 436    | 328   | 163   | 117   | 114     | 119        | 232      | 291       | 423       | 3,440   |
| Phthisis, .       | 492      | 431       | 482    | 507    | 463   | 406   | 426   | 470     | 463        | 453      | 415       | 513       | 5,581   |
| Bronchitis, .     | 109      | 135       | 173    | 147    | 92    | 62    | 62    | 70      | 84         | 111      | 109       | 122       | 1,276   |
| Heart diseases, . | 278      | 233       | 273    | 279    | 289   | 235   | 266   | 245     | 210        | 271      | 237       | 299       | 3,115   |
| Total, .          | 1,275    | 1,159     | 1,394  | 1,372  | 1,173 | 929   | 872   | 899     | 876        | 1,060    | 1,052     | 1,360     | 13,430  |
| All causes, .     | 3,237    | 3,064     | 3,516  | 3,573  | 3,353 | 3,121 | 4,224 | 4,213   | 3,650      | 3,368    | 2,984     | 3,474     | 41,777  |

## 1890.

|                   |       |       |       |       |       |       |       |       |       |       |       |       |        |
|-------------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|--------|

| Total, .          | 3,571 | 1,795 | 1,753 | 1,551 | 1,417 | 986   | 882   | 900   | 902   | 1,051 | 1,209 | 1,328 | 17,345 |
| All causes, .     | 6,309 | 3,896 | 4,161 | 3,990 | 3,786 | 3,197 | 4,565 | 4,717 | 3,664 | 3,484 | 3,357 | 3,636 | 48,762 |

An examination of these tables shows quite plainly the sharp rise in the mortality from influenza with a coincident rise in the mortality from pneumonia, phthisis, bronchitis and heart diseases in the winter of 1889-90, culminating in January; another epidemic of less magnitude in the spring of 1891, culminating in April and May, and the still greater epidemic of the winter of 1891 and '92 culminating in January, 1892.

These, together with other minor causes, increased the mortality of January 1892 to 6,309 deaths which was greater by 2,246 than the mean monthly mortality of the year, and greater by more than 1,000 than the mortality of any month in the ten-year period (1883-1892).

*Hydrophobia.*—The mortality from this cause which had attained to considerable numbers in 1889 and 1890, again fell to a single death in 1892.

During the six years ending with 1887 there had been no reported deaths from this cause. There were then 2 deaths from hydrophobia in 1888, 14 in 1889, 17 in 1890, 9 in 1891 and 1 in 1892.

The whole number of deaths from this cause for the period of registration ending with 1892 (fifty-one years and eight months) was 116, of which number 96 or 82.8 per cent. were males and 20 were females.

### *Mortality of Cities.*

The rapid growth of the urban population in Massachusetts as contrasted with that of the smaller towns is a sufficient reason for publishing in a separate table the number of deaths from all causes together with those from the principal infectious diseases in each city in the State.

By this table it appears that the total number of deaths in the cities in 1892 was 32,202 as compared with 30,049 in 1891, and those in the towns were 16,560 as compared with 15,136 in 1891.

The population of the 30 cities including Medford and Everett, by the census of 1890 was 1,394,444 or 62.3 per cent. and that of the towns was 844,499 or 37.7 per cent. of the total population, while a half century earlier, the census showed that the cities (or places having more than 10,000 in each) constituted less than one-fourth of the population.

*Deaths 1891 and 1892, Mean Death-rate of Five Census Years, and Deaths from Certain Infectious Diseases, 1892, in the Urban Population of Massachusetts.*

| Number.                | Total Deaths, 1891. | Total Deaths, 1892. | Mean Death Rate, Five Census Years (1870-90). | Small-pox. | Measles. | Scarlet Fever. | Diphtheria and Group. | Typhoid Fever. | Cholera Infantum. | Consumption. | Pneumonia. | Whooping-cough. |

| The whole State.       | 45,185              | 48,762              | 19.7                                          | 2          | 88       | 660            | 1,455                 | 827            | 1,294             | 5,739        | 5,020      | 248             |

The growth of the cities included in the foregoing table was approximately at the rate of  $3\frac{7}{10}$  per cent. per year for the period 1885 to 1890. While that of the remainder of the State was at the rate of only  $1\frac{6}{100}$  per cent. (geometric rate).

Estimating the growth in 1892 at the same rates for these two classes of the population, the mortality rates from the principal diseases included in the foregoing table are presented in the following table. In the two lower lines the mortality rates are reduced to a standard of 1,000 in the urban population for the convenience of comparison, and may be read as follows:—

For every 1,000 deaths from all causes in the urban population, there were 879 deaths in the remainder of the State in equal numbers living. For every 1,000 deaths from consumption in the urban population, there were 794 deaths in the remainder of the State in equal numbers living.

*Death Rates from Certain Diseases in 1892, per 10,000 of the Estimated Living Population, and the same Reduced to a Standard of 1,000 in the Urban or Dense Population.*

### *The Significance of General or Crude Death Rates.*

The crude death rate obtained by estimating the ratio of the number of deaths to the living population has been employed for many years as an index of the sanitary condition of a community, and for comparing its sanitary condition with that of other communities. While this method may be trusted in the comparison of the death rates of a nation, a State, county, city or town at different periods of time (since the age and sex distribution of communities remain fairly constant when comparisons are made for brief periods or successive years), it cannot be trusted for the comparison of

different towns, cities, States and countries with each other, when the age and sex distribution differs widely as for example, in our own State, in the case of Barnstable and Bristol counties, or Barnstable and Suffolk.

In support of this statement Dr. Farr says "Independently of other causes of variation, the mortality of different populations will differ according as they consist of numbers in various proportions at the ages at which the mortality is high or low."

"It is not too much to say that death rates calculated on the gross population are practically worthless as evidence of the sanitary conditions of communities less than entire nations." Dr. E. F. Willoughby, *Hand-book of Public Health and Demography*.

For the purpose of facilitating the methods of correcting death rates according to age and sex distribution, Dr. Ogle of the British Registrar General's office and J. Körösi, Director of Statistics of Hungary, have proposed the employment of standards of population in which a normal or standard distribution of ages and sexes is presented. For this purpose Dr. Ogle combines the populations of seven principal European countries including about 170 million inhabitants and presents a table in which the average distribution of these populations is given by sexes and age periods, the whole number of such periods being twelve. For the purpose of comparison with other countries, States, cities or smaller communities, this method has the disadvantage of requiring an amount of computation which becomes burdensome, and secondly, the age periods employed above 20 years do not correspond with those which have usually been adopted in Massachusetts and other American communities, and while there are some advantages in adopting a distribution into the periods 25-35, 35-45, etc., instead of 20-30, 30-40, etc., the differences are so slight as not to make it advisable to change the existing methods.

Körösi of Buda-Pesth suggests a method which is less cumbrous than the foregoing. He does not deem it essential for this purpose to adopt a sex distribution, but employs a distribution of ages only and divides them into four periods as follows:—

- All ages under one year.
- One to twenty years.
- Twenty to fifty years.
- All over fifty years.

For the purpose of comparison he suggests the use of a standard representing a healthy population having a constantly low death rate as is the case with Sweden.

The foregoing age periods were adopted by M. Körösi after trials with different periods. They differ somewhat from those which have been in use, but he states that it "was found to be preferable to group the first year separately, and that there was no sensible change produced by placing the next nineteen years in one single group."

### *The Returns of Medical Examiners.*

The whole number of returns of medical examiners for the year 1892, under the provisions of the inquest laws, was 2,210.

Of this number, 72 or 3.26 per cent. were deaths by homicide, 274 or 12.40 per cent. were suicides, 974 or 44.07 per cent. were deaths from accident or negligence, and 890 or 40.27 per cent. were the result of causes not due to violence, but to different natural causes and alcoholism. More than one-half of this group were from heart diseases and diseases of the nervous system usually of a sudden character.

*Sex.* — Out of the whole number of deaths returned by the medical examiners 1,642 or 74.3 were those of males, 560 or 25.3 were of females, and the sex of 8 was not stated.

The following summary presents the data of these cases by sexes for the period of eight years (1885–92).

| YEARS.            | SEX.   |               |          |               |              |               | Totals. |
|-------------------|--------|---------------|----------|---------------|--------------|---------------|---------|
|                   | Males. | Percent-ages. | Females. | Percent-ages. | Unspecified. | Percent-ages. |         |
| 1885, . . . . .   | 973    | 76.1          | 286      | 22.4          | 19           | 1.5           | 1,278   |
| 1886, . . . . .   | 1,027  | 74.5          | 319      | 23.2          | 32           | 2.3           | 1,378   |
| 1887, . . . . .   | 1,191  | 76.5          | 350      | 22.5          | 15           | 1.0           | 1,556   |
| 1888, . . . . .   | 1,261  | 76.4          | 373      | 22.6          | 17           | 1.0           | 1,651   |
| 1889, . . . . .   | 1,253  | 75.8          | 388      | 23.4          | 13           | 0.8           | 1,654   |
| 1890, . . . . .   | 1,303  | 73.5          | 449      | 25.3          | 21           | 1.2           | 1,773   |
| 1891, . . . . .   | 1,362  | 74.0          | 457      | 24.8          | 21           | 1.2           | 1,840   |
| 1892, . . . . .   | 1,642  | 74.3          | 560      | 25.3          | 8            | 0.4           | 2,210   |
| Totals, . . . . . | 10,012 | -             | 3,182    | -             | 146          | -             | 13,340  |
| Means, . . . . .  | -      | 75.0          | -        | 23.8          | -            | 1.2           | -       |

The first bars upon the stream above North Billerica begin about eighteen hundred feet from the dam, where there is a narrow rocky channel extending for a distance of five hundred feet up-stream. About four hundred feet above its upper end and about half a mile from the dam is the Fordway bar, which extends for a distance of seven hundred feet up-stream. About six hundred feet above the Fordway bar is Pollard's bar, which is about half as long as the Fordway bar and at a considerably lower level. The total fall over these bars in the morning when the water was flowing over the flashboards at the dam was found to be only about three inches, and any improvement which could be made at these bars with the sum which would be available would have been sufficient to lower the water only a very small amount at this place unless there was also a lowering of the dam.

In the course of the investigations it was learned that during the summer season the quantity of water which can be utilized in daytime at the dam is limited by the obstruction caused by the Fordway bar and the narrow rocky channel below it. Owing to these obstructions the mills cannot use in the daytime the full flow of the river during the twenty-four hours, for a portion of it runs to waste over the flashboards at night. If these obstructions should be partially or wholly removed, the mills could use a greater proportion of the total flow of the river and the water power would be benefited thereby. There was some question, therefore, whether in view of this benefit the mill owners might not be willing to lower their flashboards by an amount dependent upon the improvement of the channels, and in case such an arrangement had been made the river above the Fordway bar would have received the full benefit of the lowering of the flashboards and a slight additional lowering due to the greater capacity of the channel through the bar; but the bars in the vicinity were found to be composed of hard material which would have been expensive to move and would have limited the improvement in the rest of the river to such a degree that a satisfactory and permanent improvement of the channel above could not have been made with the amount of money available; and in view of all the circumstances the conclusion was reached that the money could best be spent in dredging the bars in the river farther up.

Several plans were considered, one of which provided for cutting a channel thirty feet wide on the bottom through the bars in Concord below the Assabet River, and twenty feet wide on the bottom through the bars above the Assabet, as far as the bar just above Farm bridge. The bottoms of these channels were to be five feet below the water level after the improvement had been completed; but it was not proposed to make any channel through a few bars where the depth was about four feet, as the depth of water over these bars was so great that they did not obstruct the flow of the water in more than a slight degree. A depth of five feet was decided upon to prevent the future obstruction of the channel by weeds.

## WATER SUPPLY AND SEWERAGE.

The general law giving to the State Board of Health supervision of inland waters, and imposing certain duties upon the Board in relation to water supplies and systems of sewerage and sewage disposal has been so frequently quoted in the recent reports of the Board that it is not essential to quote the statute again in full.

Acting under the Statutes of 1888 the work of the Board in this direction has been conducted during the past year in the same manner as in previous years. This work now constitutes a very important branch of the operations of the Board.

The report of this department of the Board for 1893 comprises the following topics:—

The advice of the Board to the authorities of cities, towns and corporations and individuals upon proposed or existing systems of water supply and sewage disposal under the provisions of section 3 of chapter 375 of the Acts of 1888.

A continuation of the examination of water supplies, comprising the results of chemical and microscopical examinations of public water supplies. The examination of the waters of the following rivers, the Blackstone, Charles, Merrimack, Nashua, Neponset, Housatonic and Taunton were continued and other examinations were made of the Charles, Deerfield, Shawsheen and Ware and the Nashua and its tributaries in connection with the investigations for a Metropolitan water supply.

In the summary of water supply statistics it appears that 146 cities and towns, having a total population of 1,949,455, were provided with water supplies, the majority of these places having in each a population of over 4,000. There were also 206 towns which were not provided with public water supplies only one of which had a population of more than 4,500.

The total population of places not supplied was 289,488 or but little more the one-eighth of the population of the State.

The paper by Professor Drown upon "the Amount of and Character of Organic Matter in Soils and its Bearing on the Storage of Water in Reservoirs," has a practical bearing upon all water supplies where artificial storage basins are constructed by impounding water in valleys and meadows having a surface either partially or wholly of loam or peat.

Mr. Geo. W. Fuller, biologist in charge of the Lawrence Experiment Station, details the work performed at the station during the sixth year of its existence. The principal topics treated of in his report are the character of the sewage used for experiment, the average purification attained, the permanency of filters, their management, experiments upon rapid filtration of sewage from which the sludge has been removed, sub-surface application of sewage, experiments with sand clogged by sewage, effect of polarite in removing color of dye-stuffs in sewage, removal of bacteria, work of the sewage filters in 1893, filtration of water, effects of rate of filtration, depth of material, size of sand grains, scraping, disturbing upper layer of filter, removal of layer of loam, freezing surface layers, rapidly filling from below, amount of loss of head and method of application of water upon its bacterial purification. A detailed account is given of the work of the water filters during 1893 together with the chemical and bacterial analyses of the water supplied and of the effluent water of the Lawrence city filter for the first seven months of its operation.

Hiram F. Mills, C.E., member of the Board, presents a description of the "Filter of the Water Supply of the City of Lawrence and its Results," and shows in this paper, —

1. "The insufficiency of the self-purification of streams.
2. The ready conveyance of typhoid fever down a stream by sewage-polluted drinking water.
3. The practicability of protecting a community against an infected drinking water supply by natural sand filtration."

The paper entitled "Sewage Purification of Cities and Towns in Massachusetts" presents a brief description together with chemical analyses of sewage and effluents from the systems in use in the following places: Amherst, Norfolk county jail, Framingham, Gardner, Lenox, Marlborough, Medfield, Wellesley College and Westborough.

Mr. Allen Hazen, the chemist in charge at the Experiment Station at Lawrence in 1890-93, was appointed as chemist of the department of water supply, sewerage and fire protection at the World's Columbian Exposition at Chicago, and presents in this volume a description of the process there employed for disposal of the sewage of the Exposition by precipitation and the results attained by this process.

## METROPOLITAN WATER SUPPLY.

Within the period of the past forty years or more and since the beginning of the general introduction of a public water supply into Boston the growth of the city has been rapid, and this growth has extended outward, until the suburban municipalities have acquired a population nearly as large as that of the city, the whole district within ten miles of and including Boston containing nearly a million inhabitants.

Public water supplies have now been introduced into each of the twenty-eight cities and towns embraced within this limit. The rapid growth of the towns has not only been attended with an increase in the absolute consumption of water in the district, but the relative or *per capita* consumption has also been considerably increased. To supply this demand very much of the available territory suitable for use as sources for yielding water has been taken by the cities and towns within this district. In some instances the density of the population living upon the area of the different water-sheds has increased to such an extent as to become a serious menace to the health of the population consuming the water, in consequence of the increased pollution which usually follows a corresponding increase of population.

In the words of the present report (p. 6) "The experience of the past year (1893) has emphasized the urgent need of a new water supply for this district, as not only has the water supply of Boston and the district supplied from Mystic Lake been nearly exhausted, as above indicated, but the water supplies of a majority of the places in the Metropolitan district have been in a similar condition."

The urgent demands of the authorities of these municipalities for larger and purer supplies of water finally resulted in legislative action, and the following law was enacted by the Legislature of 1893, entrusting to the State Board of Health the duty of making a general investigation of the subject of a water supply for this Metropolitan district.

## [ACTS OF 1893, CHAPTER 459.]

AN ACT RELATIVE TO PROCURING A WATER SUPPLY FOR THE CITY OF BOSTON  
AND ITS SUBURBS.

*Be it enacted, etc., as follows:*

SECTION 1. The state board of health is hereby authorized and directed to investigate, consider and report upon the question of a water supply for

the city of Boston and its suburbs within a radius of ten miles from the state house, and for such other cities and towns as in its opinion should be included in connection therewith.

SECT. 2. The said board shall forthwith proceed to investigate and consider this subject, including all questions relating to the quantity of water to be obtained from available sources, its quality, the best methods of protecting the purity of the water, the construction, operation and maintenance of works for storing, conveying or purifying the water, the cost of the same, the damages to property, and all other matters pertaining to the subject.

SECT. 3. The said board shall have power to employ such engineering and other assistance and to incur such expenses as may be necessary for carrying out the provisions of this act.

SECT. 4. The said board shall report fully with plans and estimates to the legislature on or before the first Wednesday in January in the year eighteen hundred and ninety-five, and shall append to its report drafts of bills intended to accomplish the recommendations of the board.

SECT. 5. The total amount of money which shall be expended out of the treasury of the Commonwealth in carrying out the provisions of this act shall not exceed forty thousand dollars. The Commonwealth shall be reimbursed for the amount expended by the cities and towns which are to receive the benefit of the system recommended in the report, in proportion to the population of each.

SECT. 6. Before incurring any expense the board shall from time to time estimate the amounts required and shall submit the same to the governor and council for their approval, and no expense shall be incurred beyond the amount so estimated and approved.

SECT. 7. This act shall take effect upon its passage. [*Approved June 9, 1893.*]

---

Immediately after the passage of this Act, the Board entered upon the work of investigation, and began the necessary surveys to ascertain the best supply for the district. This work has been carried on without interruption since June, 1893.

While it is too early to publish conclusions relative to a definite source of water supply for the district, it may be said that the investigations made up to the present time indicate that an abundant supply of good water for the Metropolitan District may be obtained without excessive expenditure.

## IMPROVEMENT OF THE CHARLES RIVER.

By the provisions of Chapter 475 of the Acts of 1893, the Board of Metropolitan Park Commissioners and the State Board of Health were constituted a joint board to investigate "the sanitary condition and prepare plans for the improvement of the beds, shores and waters of the Charles River, between Charles River bridge and the Waltham line on Charles River, and for the removal of any nuisances therefrom."

The joint board, thus constituted, was authorized to employ engineers and experts and to incur necessary expenses not exceeding \$5,000.

This act recognizes the existence of conditions in the specified portion of the river which have for a long time constituted a general nuisance, offensive to the sight and smell, in consequence of the serious pollution of the river and of the daily exposure of large areas of mud flats upon which the polluting matter in the river is deposited.

To remedy this foul and unsightly condition the Board has given its attention, and after surveying the territory and areas included in the provisions of the act and investigating the sanitary condition of the contiguous population, made its report to the Legislature in May, 1894 (House Doc. 775, 1894), the time for the presentation of the report having been extended by Chapter 57 of the Resolves of 1894.

The plan proposed involves the construction of a dam and a lock at the lower portion of the estuary above Craigie's bridge, by means of which the water above the dam will be kept at a constant level. While this dam may be regarded as the principal feature of the plan, other features are worthy of note, especially the treatment of the shores of the proposed basin.

One great improvement in this region is already nearly completed, the Metropolitan Sewerage System, which, when in operation, will remove a great amount of pollution from the river.

The report of the Landscape Architects to the joint board closes as follows: — "Charles River, freed from sewage, from defiling industries, from mud flats and from mud banks, and dedicated with its borders to the use and enjoyment of the public as a drainage channel, an open space, a parkway, a chain of playgrounds and a boating course, will perform its highest possible service to the Metropolitan com-

munity, and will return to the community profits, both tangible and intangible, which will annually increase."

#### INFECTIOUS DISEASE HOSPITALS.

The subject of providing separate accommodations for hospitals for persons suffering with infectious diseases of a dangerous character has become quite prominent during the past two or three years in Massachusetts cities, and is likely to become still more a subject of paramount importance in future years.

The fact that 400 such establishments exist in England alone, and the number there is constantly increasing, is sufficient to show the estimate in which they are held in Great Britain.

In response to a demand for information upon this subject, a paper has been prepared by the Secretary for the present report, containing the most recent information upon the subject, together with a brief compilation embodying the practice of other countries in this direction.

#### SUMMARY OF WEEKLY MORTALITY REPORTS.

Under this title may be found a summary of the returns sent to the office of the State Board at the close of each week from the principal cities and towns, of the deaths which have been reported to the local Boards of Health. These returns embrace a statement of the total number of deaths, the number of deaths of children under 5 years of age, and the number from each one of the principal infectious diseases.

This system of voluntary returns keeps the State Board informed of the progress of epidemics, their outbreak and their decline, and serves as a valuable index of the health of the population, its chief advantage consisting in its frequency and the fact that the Board receives its information direct from the local authorities.

#### HEALTH OF TOWNS.

In the portion of the report devoted to the health of towns may be found a digest of the principal facts of importance gathered from the city and town reports of Boards of Health of the year 1893.

This summary also contains a table in which are stated the number of cases of the principal infectious diseases which are reported to the local Boards of Health. In addition to the cases reported another parallel column contains the registered deaths from the same causes in these cities and towns and the ratio of fatality in the State at large.

## ROUTINE WORK OF THE BOARD.

The Board, in the performance of its duties under the provisions of the Statutes, has held at least one meeting in each month during the year, with such meetings of its standing committees as were essential to the proper performance of its work. The work of the year is presented in detail under the different topics referring to the prescribed duties of the Board.

Advice has been given almost daily at the office to local Boards of Health and to individuals seeking advice upon sanitary questions, and in instances, where occasion required, visits have been made by the secretary and by the engineers of the Board to cities and towns for the purpose of making investigation and inspecting and giving advice.

One public hearing only was held during the year (on April 10, 1893) and that had reference to the taking of land for the sewage disposal of Brockton under the provisions of chapter 124 of the Acts of 1890.

The statistics of mortality have been compiled and published each week at the office of the Board in the form of a weekly bulletin, which also contains once a month a report of the work done in the line of food and drug inspection, together with the prosecutions made under the Food and Drug Acts. In addition to the foregoing, during the past year the statistics of reports of cases of infectious diseases returned under the provisions of chapter 302 of the Acts of 1893, have been introduced in these bulletins.

The following table presents certain statistical data relative to the routine work of the Board :—

## STATISTICAL TABLE FOR THE YEAR ENDING SEPT. 30, 1893.

|                                                                                            |            |
|--------------------------------------------------------------------------------------------|------------|
| Whole number of samples of foods and drugs examined during the year,                       | 6,409      |
| Samples of milk examined (included in the foregoing), . . . .                              | 3,073      |
| Whole number examined since beginning of work in 1883, . . . .                             | 53,573     |
| Whole number of samples of milk examined since beginning of work in 1883, . . . . .        | 27,076     |
| Number of warning notices issued relative to adulteration during the year,                 | 423        |
| Number of prosecutions against offenders during the year, . . . .                          | 96         |
| Number of convictions during the year, . . . . .                                           | 92         |
| Amount of fines secured during the year, . . . . .                                         | \$2,476.00 |
| Force employed at Boston, for food and drug inspection, chemists and assistants, . . . . . | 2          |
| At Amherst, . . . . .                                                                      | 1          |
| Inspectors, . . . . .                                                                      | 3          |
| Total, . . . . .                                                                           | 6          |

TABLE 1. — *Marriages, Births and Deaths in Massachusetts (1842-1894), with Population and Rates per 1,000 Living.*

| YEARS.              | Population. | Marriages. | Births. | Deaths. | Excess of Births over Deaths. | Persons Married to 1,000. | Births to 1,000 Persons. | Deaths to 1,000 Persons. | Excess Rate of Births over Deaths. |
|---------------------|-------------|------------|---------|---------|-------------------------------|---------------------------|--------------------------|--------------------------|------------------------------------|
| *1841-42, . . . . . | 783,116     | 5,742      | 8,571   | 9,544   | -                             | -                         | -                        | -                        | -                                  |
| *1842-43, . . . . . | 806,862     | 5,807      | 8,750   | 10,684  | -                             | -                         | -                        | -                        | -                                  |
| *1843-44, . . . . . | 831,328     | 4,304      | 14,757  | 8,338   | -                             | -                         | -                        | -                        | -                                  |
| *1844-45, . . . . . | 856,536     | 4,863      | 15,711  | 8,844   | -                             | -                         | -                        | -                        | -                                  |
| *1845-46, . . . . . | 882,508     | 5,263      | 16,486  | 12,114  | -                             | -                         | -                        | -                        | -                                  |
| *1846-47, . . . . . | 909,267     | 5,390      | 17,097  | 14,492  | -                             | -                         | -                        | -                        | -                                  |
| *1847-48, . . . . . | 936,838     | 5,287      | 16,515  | 15,009  | -                             | -                         | -                        | 17.17                    | -                                  |
| †1848, . . . . .    | -           | 4,015      | 12,540  | 12,475  | -                             | -                         | -                        | 19.58                    | 5.16                               |
| †1849, . . . . .    | 965,245     | 6,936      | 25,773  | 20,423  | 5,350                         | -                         | 26.70                    | 21.16                    | 5.54                               |

\* The statistics of the first eight years of registration are for the years ending with April 30 of each year.

† The second line of statistics for 1848 is for the eight months ending Dec. 31, 1848.

‡ The statistics for 1849 and for each of the following years are for the calendar years ending Dec. 31.

The number of applications received since July, 1886, when the act relating to water supply and sewerage first went into operation, is as follows :—

|                  |           |
|------------------|-----------|
| 1886, . . . . .  | 8         |

### RECOMMENDATIONS.

The following recommendations were made to the Legislature at the beginning of the session of 1894 :—

1. With reference to the continuance of the work of the Board under the provisions of chapter 375 of the Acts of 1888 the Board recommends the continuance of the investigations already commenced and those indicated as desirable in the report upon Water Supply and Sewerage (Senate Doc. 4, 1894).

For these purposes, and to make the necessary investigations in order to advise cities, towns, corporations and individuals in regard to the best method of assuring the purity of intended or existing water supplies, and the best method of disposing of sewage, and to carry out the other provisions of chapter 375 of the Acts of 1888, the Board estimates that the sum of \$27,000 will be required.

### 2. *As to Notification of Contagious Diseases.*

That the laws in reference to the notification of contagious diseases to certain State authorities be so amended that the law now in force in regard to small-pox shall be extended to include other diseases dangerous to the public health.

### 3. *State Vaccine Institution.*

In its Twentieth Annual Report, 1888, the State Board of Health introduced the subject of establishing in the State one or more places at which vaccine lymph could be furnished under the supervision of the State, so that regular supplies of lymph could be furnished to all State institutions, to the local authorities of cities and towns, and to such physicians as might choose to obtain their lymph from such an institution.

This plan is adopted at present in nearly all foreign countries where vaccination is practised, and with the most successful result. The plan of public vaccinal institutes has reached its highest development in Germany, where at least thirty such establishments, well equipped and under thorough administration, furnish lymph for vaccination to all who desire it. By this plan the purity of the lymph can be satisfactorily assured, and the physician or local board of health can procure it direct from the institution, thus avoiding the delay of ordering through agents and middlemen.

As a result of this plan as well as of their very thorough enforcement of the laws, Germany is to-day more free from the scourge of small-pox than any other country in the world.

The Board therefore recommends that an appropriation of \_\_\_\_\_ be made for the purpose of carrying out this plan, under the supervision of such authority as the Legislature may direct.

#### *4. As to Vital Statistics.*

That, inasmuch as an intimate study and knowledge of the vital statistics of a community are the basis of wise sanitary administration, the data gathered annually by the Secretary of the Commonwealth, in accordance with the provisions of existing statutes, be submitted in their entirety to the Board of Health for such consideration and report as may seem to promote most fully the public welfare. Such a course would place this State in harmony with the usage in nearly all the states of this Union having registration, and in the civilized countries of Europe.

#### *5. As to Medical Inspectors of Health.*

The following bill was recommended :—

**PROVIDING FOR THE APPOINTMENT OF ADVISORY MEDICAL INSPECTORS OF HEALTH THROUGHOUT THE COMMONWEALTH.**

*Be it enacted, etc., as follows :*

**SECTION 1.** The governor, by and with the advice and consent of the council, shall, as soon as may be after the passage of this act, divide the Commonwealth into such number of districts, to be known as health districts, as he may deem proper and necessary for carrying out the purposes of this act.

**SECT. 2.** After the division provided in the foregoing section the governor shall nominate, and by and with the advice and consent of the council, shall appoint in each health district one able and discreet person, learned in the science of medicine, to be advisory medical inspector of health in said district. Every such nomination shall be made at least seven days prior to the appointment.

**SECT. 3.** Said advisory medical inspectors of health shall hold their offices for a period of seven years from the time of their respective appoint-

ments, and shall be liable to removal from office by the governor and council at any time for cause shown.

SECT. 4. Each advisory medical inspector of health shall reside in the district to which he is appointed, and his removal therefrom shall be equivalent to a resignation of his office. His powers and duties shall be advisory only. He shall inform himself respecting all influences affecting or threatening to affect injuriously the public health within the district, and shall promptly notify the local authorities of the existence of all conditions affecting or likely to affect the health of the district, and shall advise with said authorities as to the best methods of controlling the same.

SECT. 5. Each advisory medical inspector of health shall keep a record of his proceedings and observations, and shall annually make a report to the health authorities of each city or town within his district touching matters affecting said city or town, and shall transmit a copy of each report to the State Board of Health on or before the thirty-first day of October in each year.

SECT. 6. Each advisory medical inspector of health shall from time to time as requested furnish to the State Board of Health information touching the sanitary condition of the whole or any part of his district. He may make such reports and suggestions to the State Board of Health or to the local authorities as he may deem advisable; but shall in every instance forward to the State board a copy of any such communication with the local authorities.

SECT. 7. The governor, by and with the advice of the council, shall establish from time to time the salaries of said advisory medical inspectors of health, having reference in each district to the extent of territory, the number of inhabitants, the character of the business there carried on, and the amount of time likely to be required for the proper discharge of the duties. The salary thus established shall be paid from the treasury of the Commonwealth quarterly.

SECT. 8. This act shall take effect upon its passage.

#### EXPENDITURES.

The work of the Board is conducted under the provisions of several statutes, and for its different departments of work three appropriations are annually made, one for its general work, one for the inspection of food and drugs and a third for carrying out the provisions of chapter 375 of the Acts of 1888, relating to the protection of the purity of inland waters.

The appropriations for these different departments of work during 1893 were as follows : —

|                                                                       |             |
|-----------------------------------------------------------------------|-------------|
| For the general work of the Board, . . . . .                          | \$10,800 00 |
| For food and drug inspection, . . . . .                               | 11,500 00   |
| For work under the provisions of chapter 375, Acts of 1888, . . . . . | 27,000 00   |
|                                                                       | <hr/>       |
|                                                                       | \$49,300 00 |

In addition to these regular lines of work the Board was charged with the duty of investigating the question of a general water supply for the city of Boston and the suburban cities and towns to the distance of ten miles from the city.

For this investigation the Board was authorized to expend a sum not exceeding \$40,000, of which sum there was appropriated in 1893 the sum of \$15,000.

The expenditures under the foregoing appropriations were as follows : —

#### FOR THE GENERAL WORK OF THE BOARD.

|                                             |            |
|---------------------------------------------|------------|
| Salaries, . . . . .                         | \$4,819 96 |
| Printing, . . . . .                         | 1,325 15   |
| Travelling, . . . . .                       | 1,140 70   |
| Special investigations, . . . . .           | 488 78     |
| Postage, . . . . .                          | 207 61     |
| Books, subscriptions and binding, . . . . . | 306 68     |
| Express, . . . . .                          | 220 23     |
| Stationery, . . . . .                       | 152 42     |
| Telephone, . . . . .                        | 127 05     |
| Type-writer and library supplies, . . . . . | 19 30      |
| Office incidentals, . . . . .               | 54 72      |
| Messenger services, . . . . .               | 257 27     |
| Telegrams, . . . . .                        | 7 33       |
| Draughting wood-cuts, . . . . .             | 31 50      |
|                                             | <hr/>      |
|                                             | \$9,158 70 |

#### FOR FOOD AND DRUG INSPECTION. FOR YEAR ENDING SEPT. 30, 1893.

|                                                        |             |
|--------------------------------------------------------|-------------|
| Salaries of analysts, . . . . .                        | \$4,400 00  |
| Salaries of inspectors, . . . . .                      | 3,900 00    |
| Travelling expenses and purchase of samples, . . . . . | 1,661 75    |
| Apparatus and chemicals, . . . . .                     | 235 63      |
| Rent at Harvard Medical School, . . . . .              | 125 00      |
| Chemical analysis (by other chemists), . . . . .       | 2 00        |
| Furniture and fittings at laboratory, . . . . .        | 26 52       |
| Legal services, . . . . .                              | 45 00       |
| Printing, . . . . .                                    | 4 85        |
| Gas, . . . . .                                         | 33 36       |
| Extra services, . . . . .                              | 20 00       |
|                                                        | <hr/>       |
| Total, . . . . .                                       | \$10,454 11 |

EXPENSES UNDER CHAPTER 375 OF ACTS OF 1888. PROTECTION OF PURITY OF  
INLAND WATERS. FOR CALENDAR YEAR 1893.

|                                                                       |                    |
|-----------------------------------------------------------------------|--------------------|
| Salaries, including wages of laborers at Lawrence Experiment Station, | \$22,743 40        |
| Apparatus and materials,                                              | 1,896 73           |
| Rent of rooms at Massachusetts Institution of Technology,             | 900 00             |
| Rent of Lawrence Experiment Station,                                  | 125 00             |
| Travelling expenses,                                                  | 195 81             |
| Express charges,                                                      | 420 95             |
| Use of tools and office, Lawrence Experiment Station,                 | 412 32             |

## WATER SUPPLY AND SEWERAGE.\*

---

[Report required by the provisions of chapter 375 of the Acts of 1888, entitled "An Act to protect the purity of inland waters, and to require consultation with the State Board of Health regarding the establishment of systems of water supply, drainage and sewerage."]

The following report contains the substance of the replies made by the Board to those cities, towns, corporations and individuals which have applied to the Board for its advice relative to systems of water supply, drainage and sewerage, under the provisions of chapter 375 of the Acts of 1888. It also includes a summary of the work done by the Board in connection with the examination of water supplies and rivers, and the purification of sewage.

As one result of the studies of the Board, in connection with the investigations made at the Experiment Station, there has been constructed during the past year by the city of Lawrence a filter-bed covering an area of two and a half acres which now filters the domestic water supply for about 47,000 people. This water supply is derived from the Merrimack River, which receives the drainage of a large part of New Hampshire, and the sewage of Lowell enters only nine miles above the intake of the Lawrence water works. There has been in past years a great increase in the number of deaths by typhoid fever in Lowell and in Lawrence in the late fall and winter months, after the disease had spent its force and nearly ceased in the towns and cities up the river.

The studies of the Board led them to conclude that this large number of deaths, often, in Lawrence, exceeding the number in the city of Boston in the same months, was due to disease germs brought down the river and distributed to the citizens in their drinking water; and after making filters at the Experiment Station that removed all the disease germs

---

\* The first pages of this report were contained in a report made to the Legislature Jan. 10, 1894 (Senate Document, No. 4). A portion of the report then made, relating to the work done at the Lawrence Experiment Station, is not reproduced, because a more complete account of the work done at this place will be found in a subsequent part of this volume.

put into the water applied to them, the Board advised the city of Lawrence to construct a filter under the direction of the Board, and to purify their drinking water. The filter was commenced in the fall of 1892, and finished, at a cost of about \$65,000, in September, 1893. Since September 20 all the water that has been pumped to the city reservoir has first passed through the filter.

Very frequent examinations of the water show that 98 per cent. of all of the bacteria in the river water applied to the filter are removed directly by it, and in addition to this it removes a large part of the organic matter from the water and converts much of it to mineral matter, thus depriving the remaining bacteria of food material and rendering the conditions of life so unfavorable that the bacteria decrease as the water goes on through the reservoir and through the distributing pipes, until when the water reaches the citizens there remains but one-half of 1 per cent. of the number of bacteria in the river water; that is,  $99\frac{1}{2}$  per cent. of all have been removed.

The experiments of the Board indicate that the small numbers remaining are of a few hardy kinds that are not known to be in any way injurious to health; and leave the strong probability that all the disease-producing germs have been removed.

The result upon the health of the people of Lawrence is very marked and very satisfactory. The number of deaths from typhoid fever in Lawrence for the three months of October, November and December during the past five years has averaged eighteen; the number of deaths this year, since the water has been filtered, in the same three months, has been four.

At the end of the year 1893 all of the 30 cities in the Commonwealth, and 116 towns out of a total of 322, were provided with a public water supply. The total population of the communities having a public water supply is 87.1 per cent. of the total population of the State.

There are now but 6 towns which, by the census of 1890, had a population exceeding 4,000, which are not provided with a public water supply. The names of these towns, with their respective populations in 1890, are as follows: Black-

stone, 6,138; Ipswich, 4,439; Millbury, 4,428; Winchendon, 4,390; Rockport, 4,087; and Barnstable, 4,023.

Twenty-eight cities and 67 towns, having together a total population of 1,704,510, own their water works, while 2 cities and 49 towns, with a total population of 244,945, are supplied by private companies.

The flow of the streams in the year 1893, taken as a whole, as indicated by the volume of water flowing in Sudbury River, has been a very little below the average for a long series of years; but the seasonal distribution of the flow has been very uneven, the year resembling in this respect 1891. During the four months from February to May, inclusive, the flow was 23 per cent. above the average, and greater than in all but three of the previous eighteen years. On the other hand, the flow for the six months from June to November, inclusive, was 46 per cent. below the average for these months, and there were only four years of the previous eighteen when the flow during the same months was lower.

A year of this unusual character affects very differently different classes of water supplies. Those communities having sufficiently capacious ponds or reservoirs to store the whole amount of water flowing in the spring, obtained for use about the average yield of their sources of water supply; while those provided with smaller ponds or reservoirs, so that they could not prevent the spring flow of the streams from running to waste, felt much more severely the effect of the drought of the succeeding six months. The city of Boston practically exhausted the water in its Sudbury River reservoirs, but the fall rains fortunately came in season to prevent any shortage of water. Mystic Lake, which supplies Charlestown, Somerville, Chelsea and Everett, was reduced to so low a level that temporary pumps were used for a short time to pump water from the lake into the aqueduct.

These are only examples of what occurred in many places in the State. In the southern part of the State there was even less rain than in the eastern part, and some places, of which Southbridge and Uxbridge may be mentioned as examples, entirely exhausted the water from their usual sources of supply, and were obliged to resort to pumping water from the neighboring rivers, thus introducing into the pipes water of undesirable quality.

The State Board of Health was authorized and directed, by chapter 459 of the Acts of 1893, to investigate, consider and report to the Legislature of 1895 upon the question of a water supply for the city of Boston and its suburbs within a radius of ten miles from the State House, and for such other cities and towns as in its opinion should be included in connection therewith.

The experience of the past year has emphasized the urgent need of a new water supply for this district, as not only has the water supply of Boston and the district supplied from Mystic Lake been nearly exhausted, as above indicated, but the water supplies of a majority of the places in the Metropolitan district have been in a similar condition.

The Board began considering the subject of a water supply for the Metropolitan district seven years ago, by collecting information of a general character with regard to the various sources which might furnish a water supply for this district, and by determining the exact quality of the water of the different sources by a series of analyses covering a period of two years or more.

Owing to these preliminary studies, the Board was enabled to begin at once, after the passage of the act above mentioned, to enlarge its staff of engineers, and to make surveys and examinations with a view to determining definitely the capacity of different sources and the cost of obtaining a water supply from them.

While it is too early to present any conclusions regarding the best source of water supply for the district, it may be said that the investigations made up to the present time indicate that an abundant supply of good water for the Metropolitan district may be obtained without excessive expenditure.

The comparatively low stream-flow of the last three years has made the question of additional water supplies for many towns extremely urgent, and the advice of the Board as regards the capacity and fitness of new sources of supply has been repeatedly sought. The constantly increasing fund of information which the Board is acquiring through its staff of engineers, chemists and biologists, concerning the characters of the natural waters of the State, puts it in

position to give advice, in many cases, with a certainty and promptness that was not possible before these investigations were undertaken.

The chemical and microscopical analyses of the waters of the State have been continued during the year 1893, 1,731 samples of water having been examined. These examinations include many of the regular water supplies of the State, but a very much larger number of examinations than ever before has been made of waters proposed for new supplies of cities and towns.

Following is a classified list of the waters examined during the year : —

|                                                                                                                                           |       |       |
|-------------------------------------------------------------------------------------------------------------------------------------------|-------|-------|
| From open and covered reservoirs for the storage of ground waters, . . . . .                                                              | 26    |       |
| From ground-water supplies, . . . . .                                                                                                     | 294   |       |
| Special investigations of regular water supplies affected by tastes, odors, etc., . . . . .                                               | 16    |       |
| From ponds and storage reservoirs and their inlets, . . . . .                                                                             | 578   |       |
| From streams and miscellaneous sources, . . . . .                                                                                         | 127   |       |
|                                                                                                                                           | <hr/> |       |
| Total from regular water supplies, . . . . .                                                                                              |       | 1,041 |
| In connection with investigations of new sources of water supply, . . . . .                                                               | 230   |       |
| With reference to pollution of streams, . . . . .                                                                                         | 155   |       |
| With reference to sewage purification at Framingham, Marlborough, Gardner, Medfield, Westborough, Lenox, Amherst and Wellesley, . . . . . | 251   |       |
| In connection with the study of epidemics, . . . . .                                                                                      | 18    |       |
| Miscellaneous, . . . . .                                                                                                                  | 36    |       |
|                                                                                                                                           | <hr/> | 690   |
| Total, . . . . .                                                                                                                          |       | 1,731 |

The microscopic vegetable and animal organisms have been determined as usual in all the waters which have been examined chemically, and our knowledge of the connection between these organisms and the tastes and odors of the waters, has been somewhat increased.

The continued investigation of the efficiency of sewage purification throughout the State by the chemical and biological examination of sewages and effluents, and by the mechanical analysis of soils, has afforded important results, which, taken in connection with the experimental work at

the Board's Experiment Station at Lawrence, can be directly utilized in determining rules of practice for the purification of sewage by intermittent filtration on a large scale. A very large number of examinations of sewage and effluents has been made from the purification fields at Framingham, Marlborough, Gardner, Medfield, Westborough, Lenox and Wellesley. No sanitary question is of greater or more immediate importance than the disposal and purification on land, of the sewage of cities and towns. To do this effectively and harmlessly, an intelligent control of the process is needed for each situation.

In connection with the study of new sources of supply, a large number of ground waters has been examined, with the result of adding much to our knowledge of the subterranean waters of the State. In the report for 1892 attention was directed to the presence of iron in some ground waters, which made them very objectionable for domestic use. During the past year the metal manganese has been found in well waters at Watertown in considerable amount, associated with organic matter. The sanitary significance of this occurrence has yet to be determined.

In previous reports of the Board attention has more than once been drawn to the fact that the deeper layers of water in ponds were stagnant during the warmer months, and that when the bottom of the pond or reservoir contained decomposable organic matter the water near the bottom became very foul with the products of putrefaction. In the case of Lake Winnipiseogee, samples taken during August at a depth of 110 feet from the surface showed the water to be of the same quality and composition at the bottom as at the surface.

Analyses of soils from a proposed storage reservoir have been made to determine the amount of stripping which would be necessary to remove all the organic matter from the surface before filling the reservoir with water. The cleaning of the bed and sides of a reservoir is now known to be essential if the water contained in it is to be preserved free from putrefactive products in summer; but the depth to which the surface soil should be removed can be best learned by a direct determination of the organic matter in the different layers. The results of the analyses in this case are interesting and valuable.

An extended series of analyses of the water of the lower Charles River has been made during the year to determine the amount of its pollution by sewage and manufacturing wastes, and also to determine the influence of the flood tide in backing up the impure water.

During the year the artificial ice made for sale in the State has been investigated, chemically and biologically. A special report on the subject was made to the General Court on May 16, 1893.

Of the sewage filters at the experiment station, several of those that had been in use for five or six years had for a year or more been subject to treatment known to be unlikely to give the best results, but tried for the purpose of learning the result of peculiar methods of treatment, and the effluent was not as well purified as in former years. Upon restoring the old filters to their normal condition and treating them by the methods which had been found most favorable for complete purification they resumed their former ability, and gave as satisfactory effluents, both in quality and quantity, as in former years.

In the filtration of sewage remarkable results have been obtained through the past year, by first filtering sewage very rapidly (nearly five hundred thousand gallons per acre daily) through gravel stones through which air was also being constantly drawn; and then again filtering this effluent through sand at the rate of about one million gallons per acre daily. By the first filtering about 82 per cent. of the albuminoid ammonia and the same percentage of the bacteria were removed; and at the end of the second filtering there remained in the effluent but  $2\frac{1}{2}$  per cent. of the albuminoid ammonia of the sewage and but two one-hundredths of 1 per cent. of the bacteria. By this method of first burning up the sludge by the help of the current of air drawn through the gravel stones nearly three times, as much sewage may be nitrified and purified with a given area of surface as has been previously purified by sand filtration.

It is desirable that experiments upon this method of filtration be continued and its limits determined.

Very good effluents have also been obtained by rapid filtration through sand of the supernatant liquid after sewage has

settled naturally and after the sludge has been precipitated by chemicals.

In water filtration very satisfactory results in the removal of bacteria have been obtained when filtering at much higher rates than formerly, even up to nine million gallons per acre daily. These results indicate the desirability of further experiments to determine under what conditions satisfactory removal of disease germs may be assured when filtering at more rapid rates.

---

### ADVICE TO CITIES AND TOWNS.

Under the provisions of chapter 375 of the Acts of 1888, entitled "An Act to protect the purity of inland waters, and to require consultation with the State Board of Health regarding the establishment of systems of water supply, drainage and sewerage," the Board is required "from time to time to *consult with and advise the authorities of cities and towns, or with corporations, firms or individuals either already having or intending to introduce systems of water supply, drainage or sewerage, as to the most appropriate source of supply, the best practicable method of assuring the purity thereof or of disposing of their drainage or sewage, having regard to the present and prospective needs and interests of other cities, towns, corporations, firms or individuals which may be affected thereby.* It shall also from time to time consult with and advise persons or corporations engaged or intending to engage in any manufacturing or other business, drainage or sewage from which may tend to cause the pollution of any inland water, as to the best practicable method of preventing such pollution by the interception, disposal or purification of such drainage or sewage: *provided, that no person shall be compelled to bear the expense of such consultation or advice, or of experiments made for the purposes of this act. All such authorities, corporations, firms and individuals are hereby required to give notice to said Board of their intentions in the premises, and to submit for its advice outlines of their proposed plans or schemes in relation to water supply and disposal of drainage and sewage;*

*and all petitions to the Legislature for authority to introduce a system of water supply, drainage or sewerage shall be accompanied by a copy of the recommendation and advice of the said Board thereon."*

During the year 1893 the Board has given its advice to the following cities, towns, corporations and individuals who have applied for such advice under the provisions of the general act of 1888, or under special acts relating to water supply and sewerage.

Replies were made during the year to applications made from the following sources for advice relative to water supply: Arlington, Canton, Chester, Fairhaven, Falmouth Heights, Holyoke, Hyde Park, Kingston, Lawrence, Lexington, Lowell, Lynn, Marlborough, Medford, Melrose (three replies), Mendon, Methuen (two replies), Newburyport (two replies), North Andover, Peabody, Rockport, Salem, Saundersville (Grafton), Scituate, Sharon, Southbridge (two replies), South Deerfield, Stoughton, Uxbridge, Wakefield, Walpole (two replies), Waltham, Webster, Westborough, West Springfield, Whitman.

Replies relating to sewerage and sewage disposal were made in response to applications from the following sources: Andover, Attleborough, Braintree, Brockton (two replies), Framingham, Holyoke, Leicester (three replies), North Brookfield, Pittsfield, Plymouth, Spencer and Westborough.

#### WATER SUPPLY.

The following is the substance of the action of the Board in reply to applications for advice relating to water supply:—

**ARLINGTON.** The committee on water supply of the town of Arlington applied to the State Board of Health, Dec. 24, 1892, for advice relative to the best method of obtaining a water supply for the higher portions of the town, which cannot be supplied from the present service, and of improving the quality of the present supply. The attention of the Board was particularly called to a plan for pumping water from driven wells, on the borders of the great meadows and near the East Lexington railroad station, to a reservoir at a

sufficient height to supply the high portions of the town. The Board replied as follows : —

Boston, Feb. 10, 1893.

In order to ascertain the quality of water from these wells, the Board has caused analyses to be made of the five samples sent in by you. These samples showed the presence of an unusually large amount of free ammonia for a ground water and a larger amount of iron than is commonly found, both of which were probably due to the proximity of the wells to the Great Meadows. Notwithstanding these characteristics, if the water drawn from this source should continue to be as good as the samples, there is no doubt that it would be satisfactory for all water-supply purposes, and very much better than the water at present supplied to Arlington. The great danger, however, is that with continued pumping the water will be derived to an increased extent from the meadow by filtration through the peaty material, and will deteriorate and become unsatisfactory.

It is obvious from an inspection of the locality where the wells are driven that very little if any water can come from the easterly or down stream side of the wells owing to the presence of rock and other impervious material, and the fall of the ground in this direction. In other directions from the wells the character of the upland which might contribute ground water to them is such that a large portion of the water flows off into the meadows, and only a comparatively small amount soaks into the ground, near enough to the wells so that it will percolate directly to them. If any large quantity of water is to be obtained from the wells, the supply must necessarily be derived from the meadow by the filtration of water through it into the ground beneath, and under such circumstances it is extremely doubtful if the supply will continue to be of satisfactory quality.

With regard to the quantity of water to be derived from this source, the character of the material encountered by the test wells and the results obtained by the pumping test seem to indicate that the ground in the immediate vicinity of the wells is of favorable character for obtaining a ground water supply. The tests have not been sufficiently extended, however, to determine from how large a territory wells at this place will draw water or how much water can probably be obtained from this source. Even if the wells should draw water from a very considerable distance, so that all the water now coming into the Great Meadows could be utilized, the average daily supply in a dry year could hardly be expected to exceed 200,000 gallons per day ; but if the water filtering through the peaty material of the Great Meadows should prove to be of

satisfactory quality the supply might be increased by diverting into the meadows some of the water from the upper half of the main watershed, which would otherwise run to waste during the spring over the dam of the main reservoir.

Taking everything into consideration the Board is of opinion that the chances are against getting a satisfactory supply from the proposed source either as regards quantity or quality, though some of the doubts which now exist might be removed by more thorough tests of this source if it were thought advisable to make them.

In view of the unfavorable outlook for obtaining a satisfactory supply from the source already tested near the Great Meadows, the Board has caused examinations to be made by its engineer of other portions of the watershed from which your water supply is derived. Judging from the surface indications he finds that some of the land in the vicinity of the main brook which feeds your reservoir promises to furnish a larger supply of ground water of good quality than any other place upon the watershed, and the Board would therefore advise that you make further tests in this vicinity. It is desirable to locate a well or wells quite a long distance, say one-fourth of a mile or more, above the present reservoir but not so far up stream as to be above the ridge, through a cutting in which Munroe Brook flows into the stream which supplies your reservoir. It is also desirable to avoid the immediate vicinity of any large swamp, and to select a place where the porous material from which water can be pumped freely extends to a considerable depth, say from thirty to fifty feet.

In addition to the question of obtaining a supply from the ground your application also refers to the deepening of the present reservoir with a view to improving the quality of the water.

The disagreeable character of the water drawn from the reservoir at times last year and also on previous occasions is caused by the growth and decay of minute vegetable forms, and these in turn grow in greater abundance when the water contains an abundant supply of nitrogenous food. Experience has shown that this supply of food may be derived from organic matter in the bottom of the reservoir or it may come into the reservoir in the water which supplies it. In the present case the supply of food for these minute organisms may be derived from both these sources, as there is a considerable amount of organic matter in the bottom of the reservoir, and analyses show that the water of the brook entering the reservoir contains a liberal supply of nitrogen, a result which might be expected from the population upon the watershed and the heavy manuring of portions of it.

The removal of all mud from the reservoir and the deepening of

the shallower portions would undoubtedly have a decided tendency to improve the character of the water. Of these improvements, however, the removal of the mud is of greater importance than the deepening of the shallower portions of the reservoir where it has a gravelly bottom; still, both of them are very desirable. There can be no certainty, however, of any radical change for the better in the quality of the water, as these improvements would only remove one of the causes of the minute vegetable growths.

**CANTON.** The water commissioners of Canton requested the advice of the State Board of Health, March 29, 1893, as to the propriety of taking an additional supply of water from the valley of Beaver Brook. To this application the Board replied as follows:—

Boston, June 2, 1893.

The State Board of Health has considered your application with regard to an additional water supply, to be taken from the valley of Beaver Brook above your present pumping station, in accordance with the report of your engineer, submitted with said application.

The report above mentioned contains the results of investigations made at various points in the valley of Beaver Brook above the present pumping station. The nearest point at which the investigations indicated the existence of a valuable additional supply is half a mile above the present pumping station, in an extensive meadow and swamp lying above Pleasant Street. Other investigations were made about a mile above the pumping station in what are known as the Ponkshire Meadows and from this point up to the vicinity of the Henry Springs, so called, and the question of taking an additional supply from Dead Meadow Brook and from York Pond, which lies at the head of Beaver Brook, was also considered.

All of these sources except the Ponkshire Meadows may furnish a valuable additional supply in the future, but the investigations in the meadow above Pleasant Street indicate that a sufficient additional supply of good water for the present may be obtained from this source alone.

The plan proposed by your engineer to meet all present requirements consists of a large collecting well about 2,600 feet above the present well, and connected with it by means of a twelve-inch pipe laid at a considerable depth below the surface of the ground. It is also proposed by him to extend pipes above the new well and to connect driven wells with them to furnish additional water.

Ten test wells were driven in the immediate vicinity of the pro-

posed collecting well and at varying distances from it, and samples of water from a portion of these wells have been analyzed by the State Board of Health. The tests in this vicinity indicate the existence of porous layers beneath the surface, through which water will flow freely; and the samples of water collected in the immediate vicinity of the proposed collecting well were of excellent quality. At a distance of a few hundred feet from this location, however, one sample was collected which contained enough iron to make the water objectionable for domestic uses, and at a somewhat greater distance in another direction an unsatisfactory water was obtained. There is therefore some doubt whether the water at the location of the collecting well will maintain its present good quality when a continuous draft on the well causes the water to flow to this point from all directions. The tests above the collecting well are limited in number and do not enable any definite judgment to be formed as to the character of the water to be obtained from the wells, which, according to the proposed plan, are to be driven to supplement the supply from the collecting well.

Taking the investigations made in this vicinity as a whole, they seem to indicate that it will be feasible to obtain a satisfactory supply of water, but they do not indicate definitely how large a territory will furnish good water, or whether the territory which furnished samples of good water will continue to furnish water of the same quality when a continuous draft is made upon it, nor can the permanent quality of the water be thoroughly tested except by producing this continuous draft, which may be done either by driving wells, connecting them together and pumping from them for a long time, or by laying the proposed main pipe and connecting the driven wells with it so that they will flow continuously. The cost of a pumping test would be so large, without adding anything of permanent value to the works, that the Board advises the laying of the main pipe as proposed by your engineer, and the connection with it of driven wells, substantially as proposed by him, in the territory where the best water can be obtained, and one or two driven wells at the site of the proposed collecting well, but it would not advise the construction of the collecting well until the test wells in its vicinity had shown by running a long time, say six months or a year, that the water from them was not deteriorating in quality. After such test the collecting well could be constructed.

CHESTER. The committee on water supply of the town of Chester applied to the State Board of Health, April 25, 1893, for its advice relative to taking the water of Austin, Walker

and Blandford brooks, in the towns of Chester and Becket, and of Horn Pond in the town of Becket. The Board replied as follows:—

Boston, June 1, 1893.

In response to your application of April 25, 1893, the State Board of Health has caused an examination to be made of four sources of water supply for Chester, namely, the Austin, Blandford, and Walker brooks in Chester and Becket, and Horn Pond in Becket.

Samples of water from all of these sources, collected by you May 22, have been analyzed. All four samples are very soft and there is no choice between them in this respect. In all other respects the analyses of samples from the Austin and Blandford brooks indicate that these waters are very nearly alike in quality, with a slight advantage in favor of the Austin Brook, and that they are decidedly better than the waters of Walker Brook or Horn Pond. An examination of Austin Brook shortly after a heavy rain showed only a moderate amount of turbidity in its water, and the absence of houses and roads upon its watershed are a point in its favor. It is therefore a very desirable source of supply to the extent of its capacity. There is obviously no reason to doubt that it will furnish the town with an ample supply of water for all ordinary water supply purposes except during very dry seasons, and judging from the yield of other mountain streams, in proportion to the territory drained by them, it will furnish a sufficient quantity of water even at such times for these purposes.

The Blandford Brook at its mouth has a watershed about one-half greater than that of the Austin Brook, and in the absence of definite knowledge its summer flow may be assumed to be one-half greater than that of the Austin Brook.

The sample of water from the Walker Brook was, as before indicated, not as good as those from the Austin and Blandford Brooks; still it would be classed as a satisfactory water in towns where there are not so many opportunities for getting a first-class water, and there is no reason now known to the Board why it should not be resorted to should the other sources fail in very dry times to furnish a sufficient supply. At such times it seems probable that the water from this brook might be as good as that from the others, but more definite information upon this point can be obtained by collecting and analyzing a sample of water from the brook when at a low stage.

The sample from Horn Pond indicates that at the time of its collection the water of this source was better than that of the Walker Brook, but not nearly as good as that of the other brooks.

The water of ponds and other quiet bodies of water is liable to be affected at times by growths of minute organisms which affect the taste and odor of the water, and which, though not known to be injurious to health, may at such times render the water unpalatable. This source would furnish a sufficient quantity of water, but owing to the reasons above indicated and to the larger cost of taking water from it on account of its greater distance from Chester, it does not seem to be a desirable source for the town to adopt.

In the following suggestions as to the source to be adopted and the general plan of works the Board necessarily bases its judgment on facts deduced from observations made in other places, and these suggestions may therefore require modification on account of the local conditions affecting the minimum flow of these streams, of which the Board now has no definite knowledge. The suggestions are that Austin Brook should be adopted as a source of supply in any case, and that if a larger amount of water than it will supply is needed it should be taken from the Blandford Brook near its mouth. If a still further supply should ever be needed, which would occur only during very extreme droughts, if at all, it should be taken from Walker Brook. Should water be taken from both the Austin and Blandford brooks it would be desirable to place the inlet at the former slightly higher than at the latter so as to insure taking the supply from the Austin Brook whenever it will furnish a sufficient quantity of water, and thereby prevent the entrance of the water from the Blandford Brook whenever it is affected by the wash from the road near it.

**FAIRHAVEN.** The authorities of Fairhaven applied to the Board, March 10, for advice in regard to introducing a water supply from driven wells in the easterly part of the town, to which the Board replied as follows:—

Boston, May 5, 1893.

The State Board of Health has considered your application dated March 10, 1893, relative to a proposed water supply for the town of Fairhaven, to be taken from driven wells in the valley of the Nasketucket River, a small stream situated about one and a half miles east of the town. At this place six test wells have been driven and are now flowing. Samples of water collected from three of these wells have been analyzed. The analysis of the water from the northeasterly well showed it to be a very pure and very soft water, while the samples from one of the intermediate wells and from the southwesterly well indicated water that had at some time been polluted and again purified by filtration through

the ground. As there are very few houses anywhere near the wells and the whole watershed is very sparsely settled, the inference to be drawn from these results is that the southerly wells intercept a vein of water which has passed near one of the nearer farmhouses. These results should not lead to the rejection of this source on the score of quality, because, not only is the water purified by its passage through the ground, but it is not improbable that when water is pumped from this source continuously it will assume much more nearly the character of the water now flowing from the northeasterly well. It would be advisable, however, in any case, if a supply is taken from this source, to determine from which farmhouse the polluting matter now enters the ground, and prevent such pollution, rather than depend upon the purifying power of the ground.

With regard to the quantity of water to be derived from wells in this locality, the tests made up to the present time do not appear to be conclusive as to whether the supply will be sufficient for the town for any considerable time in the future. Taking into account, however, the results of these tests, the comparative economy of this source on account of its nearness to the town as compared with any source from which it is at all probable that a satisfactory supply can be obtained, the opportunities for supplementing the supply whenever necessary from the Mattapoissett River valley, and the excellent quality of the water which the proposed source may be expected to furnish with proper care to prevent pollution, the Board is of opinion that this source is a proper one from which to take at the present time a water supply for Fairhaven.

It has been found by experience in this State that wells encountering ledge within 20 to 30 feet of the surface do not furnish as large a quantity of water as where the ledge is at a greater depth, and the Board therefore advises you to make further tests of the ground in this vicinity before locating the permanent wells in order to ascertain if a place cannot be found where the ground is porous enough to furnish water freely and where the ledge is at a greater depth than at the present location.

**FALMOUTH HEIGHTS.** The Falmouth Heights Water Company applied to the Board, June 13, for advice relative to taking a supply of water from a well or wells on the premises of the company at Falmouth Heights, a summer resort in Falmouth, upon Vineyard Sound. The Board replied as follows:—

BOSTON, July 6, 1893.

In reply to your application dated June 13, 1893, relative to a proposed water supply for the summer settlement known as Fal-

mouth Heights, in the town of Falmouth, the State Board of Health has caused an analysis to be made of a sample of water from a well sunk in one of the parks at the Heights, a few hundred feet north of Observatory Hill, and finds that the water is at present of excellent quality for water supply purposes.

Without further information the Board is unable to advise in regard to the quantity of water that can be obtained, and it should be examined after continued use that its permanent character may be determined.

**HOLYOKE.** The water commissioners of Holyoke applied to the Board, June 13, for its advice relative to taking the water of Munn Brook, in the town of Granville, as an additional water supply for the city. The Board replied to this application as follows:—

Boston, Oct. 5, 1893.

The State Board of Health received from you on June 13, 1893, an application for advice with regard to an additional water supply for the city of Holyoke, accompanied by a plan for taking water from Munn Brook in the town of Granville, through a pipe 20 inches in diameter, to Ashley Pond, one of the present sources of water supply of Holyoke.

The Board has caused an examination of the watershed of Munn Brook to be made, also an analysis of a sample of water collected from the brook near the proposed point of taking.

These examinations indicate that the water is soft and naturally of very good quality; but it is at present polluted at a few points by the discharge of sewage into it.

This pollution should be stopped before the water is taken for use, and as an additional precaution it is desirable that the water should be diverted into Ashley Pond rather than be allowed to run directly from the stream through the pipes into the city.

The amount of water which this source will furnish with a 20-inch pipe connection to Ashley Pond is so limited that the Board would advise the use of a pipe not less than 24 inches in diameter; and even with a connection of this size, the brook will not furnish, in very dry seasons, a sufficient additional supply for any long term of years in the future if the city continues to grow as it has in the past, unless capacious storage reservoirs are built upon it or its branches.

Certain sites for reservoirs have been indicated, but the information furnished with regard to their character, capacity, and cost is too limited to warrant an opinion as to whether it is desirable to

construct them. It has been shown, however, that it is feasible to supplement the supply to be obtained from Munn Brook by a comparatively short connection from the Westfield Little River; so that if Munn Brook should prove insufficient, there may be an opportunity to obtain a further supply from this river.

The Board has also caused an examination to be made, in a general way, of other available sources, among which may be mentioned the Westfield Little River above referred to, and Bachelor Brook in Granby, both of which would furnish more water than Munn Brook; the former by gravity, and the latter by pumping.

. Neither of the three sources which have been mentioned has such a distinct advantage over the others as to enable the Board to advise, with the information now available, as to which is the most appropriate source of water supply for Holyoke.

It is obvious that a further water supply for Holyoke is urgently needed; and in view of the fact that an adequate additional supply will necessarily require a large expenditure of money, the Board advises you to have made, as promptly as possible, with the assistance of an engineer skilled in water supply investigation, a much more thorough investigation of the available sources than has yet been made.

When this additional information is received, the Board will advise you further in this matter.

Accompanying this reply will be found a table of analyses of samples of water collected from various sources.

The water of streams varies so much from time to time that it will be advisable to have further analyses made as a basis for forming a judgment as to the relative quality of water from the different sources. The Board will cause these analyses to be made, if you will provide for collecting the samples.

**HYDE PARK.** The Hyde Park Water Company applied to the Board, May 26, for advice as to the propriety of increasing their present supply of water by the use of driven wells north of their present driven well system. The Board replied to their application as follows:—

BOSTON, June 14, 1893.

The State Board of Health has received and considered your application dated May 26, 1893, asking it to examine and report upon the quality of water from a new system of driven wells, located just north of the present driven well system in Hyde Park.

Samples of water have been collected and analyzed from three wells of this system, one being the well nearest the river, another

a well near the middle of the system, and a third the well farthest from the river. These samples were all collected by pumping with a hand pump. The water from the well nearest the river (well No. 5) gives the same indications of imperfect filtration which are characteristic of water from the starch factory well, though not to so great an extent. This water would not be of satisfactory quality for water supply purposes. The samples from the intermediate well and from the one farthest from the river (wells Nos. 14 and 36) resemble in character the water taken from your present driven well system five or six years ago and are of satisfactory quality. Just what the effect will be of continuous pumping from the wells which now furnish good water cannot be foretold with certainty. The general experience under these circumstances, however, is that the water will deteriorate. The Board would therefore advise that if you take any water from the new system of wells each well should be provided with a gate so that it can be shut off if it furnishes water of unsatisfactory quality, and frequent tests should be made to determine whether or not the water is deteriorating.

It is very desirable that in increasing your supply in the vicinity of your present pumping station water should be taken from the ground as far from the river as suitable porous material can be found.

KINGSTON. The water commissioners of Kingston applied to the Board, June 9, for its advice relative to increasing their water supply by taking the water of Jones River, in case their present ground-water supply should prove insufficient. The Board replied as follows:—

Boston, July 6, 1893.

The State Board of Health received from you on June 9, 1893, an application with regard to using water from Jones River this summer for an additional water supply if the supply from the present well and filter-gallery should prove insufficient.

The Board caused samples of water collected from Jones River at Kingston in October, 1887, and in February, 1890, to be analyzed, and these analyses indicate that the water has a rather dark color, owing to the drainage from swamps on the watershed, and that it would not be wholly satisfactory to the consumers either in taste or appearance. With regard to its relation to the health of the consumers it may be said that in a case like this a chemical analysis of the water is not a trustworthy guide. The experience of the Board has shown that a *running stream* which receives sew-

age above the point where the water is taken from it is one of the most dangerous sources of water supply; because, if the infection of any specific disease is turned into the stream, it is much more likely to be conveyed to the water works intake and thence to the consumers before it loses its virulence than if the sewage entered a large pond or reservoir where there is no current.

The advice of the Board is therefore that the town of Kingston should not use the water of Jones River even temporarily without first ascertaining by an actual inspection of the main stream and its tributaries that no sewage is turned directly into them; and it is the further opinion of the Board that this river is not an appropriate source from which to take a permanent water supply for Kingston.

**LAWRENCE.** Application was received from the Lawrence water board for information in regard to the results of filtration of the water supply of the city through the filter covering two and a half acres, built by the city during the past year at an expense of about \$65,000.

The water supply is drawn from the Merrimack River about nine miles below the entrance of the sewage of the city of Lowell, and for many years typhoid fever had prevailed in Lawrence to the extent of three times the average of the cities of the State, and following six or eight weeks after its prevalence in Lowell.

Under date of December 5, the following reply was made:—

The filter bed built by the city of Lawrence under the advice and in accordance with plans of the State Board of Health, has been steadily purifying the water supply of the city since the twentieth of September.

When commencing to construct the filter, you were advised that “with such a filter, properly managed, the experiments of the Board of Health indicate that at least 98 per cent. of all of the bacteria of the river water will, under all circumstances, be removed.” During the past two months the filter has been removing this percentage of all the bacteria of the river water, but this is not all that it accomplishes; it removes a large part of the organic matter of the river water and converts it to mineral matter, thus removing from the water the food material which the bacteria live upon, and the result is that the two per cent. of bacteria remaining after the water has passed through the filter find their condi-

tions of life so unfavorable that they decrease as the water goes on through the reservoir and through the distributing pipes, until when the water reaches the citizens there remains but one-half of one per cent. of the number of bacteria in the river water, that is, ninety-nine and one-half per cent. of all have been removed.

The experiments of the Board indicate that the small number remaining are of a few hardy kinds that are not known to be in any way injurious to health, and leave the strong probability that all disease-producing germs have been removed.

It will be a satisfaction to the citizens to know that while for the past five years the number of deaths by typhoid fever in Lawrence has averaged five for the month of October and five for the month of November, the number of deaths this year has been only one for each of these months.

**LEXINGTON.** The water company of Lexington applied to the Board, February 15, for its advice relative to an additional water supply, and the Board replied as follows:—

BOSTON, May 4, 1893.

The State Board of Health has considered your application, dated Feb. 15, 1893, asking the advice of the Board in regard to an additional water supply for the town of Lexington. This application was accompanied by the report of the civil engineer employed by you to make investigations for an additional water supply for the town, and by a plan prepared by him of proposed storage reservoirs on Vine Brook, above your present works. The attention of the Board was subsequently called by you to the covered gallery, built last year, for the collection of ground water, in the sandy plain near the village, and connected with your present ground water sources.

The report of your engineer relates to examinations for a supply from entirely new sources as well as to augmenting the present supply by additional works within the territory from which it is derived. The examinations for new sources were made in a westerly or north-westerly direction from the central village of Lexington, in territory from which the water drains toward the Shawsheen River in the town of Bedford, and extended to a point nearly two and a half miles from the village. The larger streams within this territory will not furnish directly a water of satisfactory quality for the purposes of a public water supply, and the smaller streams at the points where the water is good will furnish so little water that it would be difficult, if not impracticable, to obtain from them a sufficient quantity of water for Lexington. The test wells

driven under the direction of your engineer within this territory give unfavorable indications with regard to obtaining a satisfactory ground water supply from it.

The difficulty of obtaining a supply from any new source about Lexington, as indicated by the special examinations of your engineer in the territory mentioned, and a general examination of other possible sources, seems to warrant the adoption of measures for developing the present supply which might not be warranted if a much better source could be obtained within a reasonable distance from the town.

It is understood that your present ground water sources now furnish an ample supply of water during all but the dryer portions of the year, and that the reservoirs shown upon the plan submitted are intended to supply the deficiency at such times. The lower of the two reservoirs is considerably further up stream and about five times as large as the one proposed by you in 1891, and referred to unfavorably in the reply of the Board to you dated April 7th of that year. The present location is much better than the old one, but, owing to the fact that some of the land above the reservoir is cultivated, and that so small a quantity of water will flow into it owing to the limited size of its watershed, much care will have to be taken to maintain the water in a pure and satisfactory condition. In the preparation of the reservoir all soil and vegetable matter should be removed from its bottom and sides, and the shallow portions should be deepened. A liberal amount of land should be acquired around the reservoir for its protection, and suitable arrangements should be made to prevent any washings from manured fields from flowing into it. It would also be necessary to take proper measures to prevent any contamination of the water by the drainage from a large stable at the extreme upper end of the watershed.

The upper reservoir is less satisfactory than the lower one as it is shallow and has so small a watershed that the water would stand in it a very long time before being replaced by fresh water, and it would probably become unfit for use. If, therefore, you decide to increase the supply by storing the surplus water which flows off during the wetter portions of the year, the Board would advise that the upper reservoir should not be constructed and that the lower one should be enlarged as much as possible by locating the dam somewhat further down stream, and by excavating within the reservoir. The suggestion of your engineer that "some additional ground water might be brought into the pump well by laying an open-jointed sub-drain in the trench with the leading main from the reservoir, making the joints tight wherever the pipe passed

through a muck deposit," is one worthy of adoption should the portion of the pipe trench through the sandy land toward the proposed reservoir be found to furnish water freely.

An analysis has been made of a sample of water collected from your covered gallery near the village, and the water is at the present time of satisfactory quality for domestic use. At the time the sample was collected water was not being drawn from this source, and as its quality may change when there is a draft upon it you are requested to notify the Board when you begin to use it, and further examinations will be made.

**LOWELL.** The Water Board of Lowell applied to the State Board of Health, May 9, for its advice relative to taking an additional supply of water from the valley of River Meadow Brook in the south part of Lowell. The Board replied as follows:—

Boston, May 16, 1893.

Samples of water from driven wells in this locality were sent in to the Board by your engineer last autumn, and the water was then found upon examination to be of excellent quality for all the purposes of a public water supply. This portion of the city, however, is growing rapidly and in order to maintain the purity of the water, if a supply is taken from this source, the city should control the land for a considerable distance from the wells in all directions so as to prevent the construction of buildings near them, and should extend the sewerage system of Lowell so as to carry away from all buildings the sewage which might otherwise find its way by filtration through the ground into the wells.

The time within which you desire a reply is too limited to permit the Board to make sufficiently extended investigations to serve as a basis for an opinion as to the quantity of ground water which can be obtained from the valley of this brook within the limits of the city of Lowell, nor does such an opinion seem necessary at the present time when you are constructing extended works by which the capacity of this source can be tested.

**LYNN.** The mayor of Lynn applied to the State Board of Health, January 31, for its advice relative to taking the water of Saugus River and its tributaries as an additional supply for Lynn. The Board replied as follows:—

Boston, April 4, 1893.

The application is not limited to any particular portion of the river and its tributaries, but the attention of the Board has been

directed chiefly to the territory above Howlett's dam, to which the works of the Lynn water supply now extend. Above this point on the river are situated the towns of Wakefield and Reading which turn so much polluting matter into the streams as to render the Saugus River at this point an unfit source from which to take a water supply, unless the water is very thoroughly purified by filtration. This polluting matter enters Quannapowitt Lake and its tributaries and the streams which flow through Wakefield and enter the river below the town. If these polluted waters were diverted, those coming from the remaining portions of the watershed would be comparatively free from pollution by sewage.

No extended chemical examinations of these unpolluted sources have been made, with the exception of Pilling's Pond, but judging from an examination of the water at this season of the year and a few previous analyses, it seems probable that some of the water, particularly that from the river itself, would be unsatisfactory for water supply purposes, owing to the large amount of swampy land with which the water comes in contact, thereby making it very dark in color and giving it a peaty taste and odor.

Pilling's Pond is an artificial millpond made by flowing a meadow to a depth of four feet. The State Board of Health in 1888 advised the Revere Water Company that this pond was not a suitable source of supply for the towns of Revere and Wintthrop, owing principally to the fact that if used as a principal source of supply it would necessarily be drawn very low in the summer. The water, however, is of fairly good quality considering the very small depth of the pond and it might be used by Lynn in connection with present sources until a better supply can be obtained.

There is a very large amount of flat land adjacent to the river between the dam at Montrose and Lake Quannapowitt and it seems not improbable that a valuable ground water might be obtained from this territory, although there are no means of determining at all definitely at the present time either the quantity or the quality of water which could be obtained. It is not improbable, however, that the quality of the ground water would be very much better than any surface water supply from this vicinity and the quantity may be as large as would be furnished by the surface water sources after excluding the polluted water of Lake Quannapowitt and the brook which receives the drainage of Wakefield.

The Board recognizes the gravity of the present situation of the Lynn water supply and would therefore advise that provision should be made at the earliest possible moment for supplementing the present supply with the best water which can be obtained from the Saugus River watershed.

In order to provide any other than a very temporary supply of potable water from the Saugus River valley, it is obvious that the works must necessarily be somewhat complex and expensive, and it is not at all probable that a fairly permanent supply can be obtained from this source. The Board would therefore advise that before entering upon any extensive works in this valley, the whole subject of a further water supply from this valley, and from other available sources, should be carefully investigated. One of the first points in such an investigation should be the examination of the territory near the river, between the Montrose dam and the next dam above, with a view to obtaining a ground water supply.

The Board has now before it an application from the Wakefield Water Company, asking for advice with regard to an additional water supply for the towns of Wakefield and Stoneham, to be taken from filtering galleries, wells or basins, upon the banks of that portion of the Saugus River lying within the limits of the town of Wakefield, above the milldam at Montrose. The Board is aware of the fact that the Wakefield Water Company has practically reached the limit of capacity of Crystal Lake, its present source of supply, and that the other source, viz., Lake Quannapowitt, from which the water company was originally authorized to take a further supply, is not of suitable quality for water supply purposes. It is therefore of opinion that the right of Lynn to take water from the Saugus River valley should be so far restricted as not to prevent these towns from receiving from it as much water as may be needed for their supply, in addition to the quantity of water which Crystal Lake will furnish.

It is not feasible from present information as to the amount of water which can be obtained from different places, to make a fair apportionment of the territory between Lynn and these towns; the Board therefore concludes that Lynn should be granted the right to take water from any portion of the valley of Saugus River, not already granted by the Legislature to some other town or water company; but that this grant should be subject to the restriction that the towns of Wakefield or Stoneham, or the company supplying them with water, may be authorized to take water from this valley at any point within the limits of the town of Wakefield, and to the extent required to furnish in connection with Crystal Lake, the present source of supply, a supply of water for these towns. In connection with this restriction it would, of course, be fair to provide that whenever these towns, or the company supplying them with water, take a supply from any source in the Saugus valley other than those already controlled by the Wakefield Water Company, they should be required to pay to the city of Lynn a fair

proportion of the amount already paid by said city for water or land damages, and if they should utilize to any extent works previously constructed by the city, they should pay a fair proportion of the cost of these works.

The Board thinks it proper that a further application should be made for its advice when you can define more specifically the sources from which it is proposed to take water, and have by preliminary surveys and estimates obtained the facts which are essential as a basis for a proper decision as to the relative merits of different sources. With this further application in view the Board will co-operate with you by causing analyses to be made from time to time of the water of the various proposed sources.

**MARLBOROUGH.** The water commissioners of Marlborough applied to the Board, April 28, for its advice relative to constructing a new storage reservoir upon Millham Brook in the west part of Marlborough, near the Northborough line, and as to the probable quality of the water of such proposed reservoir at the end of eight years. The Board replied as follows:—

Boston, July 8, 1893.

The State Board of Health has carefully considered your application, dated April 28, 1893, with regard to constructing at once the proposed storage reservoir on Millham Brook in the vicinity of your new pumping station. You state in your application that you will not need the proposed reservoir for eight years or so and that you wish for the advice of this Board as to the probability of obtaining good water from this proposed reservoir after being flowed fifteen feet deep for a period of eight years without removing any of the soil.

A careful examination of the experience with all artificial reservoirs in the State which have not had the soil removed from them and which in other respects are at all comparable with the proposed Marlborough reservoir shows that in some of these reservoirs the water was bad every summer, not only for eight years after they were first filled but for a much longer time. A typical instance of a reservoir of this kind is the Ludlow reservoir at Springfield which was used for sixteen years and then practically abandoned for a new source of supply. Other reservoirs somewhat similar in character, although they may have furnished bad water when first filled, soon began to improve, and at the end of five, eight or ten years furnished very much better water than at first. The chances as to whether the water will continue to be bad or will improve materially at the end of eight years seem to be about even.

The experience with reservoirs which have been thoroughly cleaned by the removal of all soil and vegetable matter from their bottom and sides, although somewhat limited, has been extremely favorable, and from our present knowledge we should expect much better results from a thoroughly cleaned reservoir soon after it is filled than from an uncleaned reservoir eight years after filling.

The Board recognizes that the element of cost is an important factor in determining what should be done, and as the Board has no accurate information upon this point it cannot now advise definitely as to what should be done in the matter of constructing the reservoir. It would advise, however, that a careful estimate of the cost of thoroughly cleaning the reservoir should be made and would urge the adoption of this method of construction if it is found to be practicable.

**MALDEN, MEDFORD AND MELROSE.** For many years these suburban places have used Spot Pond as a source of water supply, but owing to the rapid growth of these communities the pond was drawn to a much lower level at the end of 1892 than ever before. The city of Malden has for several years taken a supplementary supply from driven wells in the easterly portion of the city, but the other two places were at this time wholly dependent upon Spot Pond for water. On Feb. 9, 1893, the Board addressed the following communication to each of the water boards of Malden, Medford and Melrose, with reference to the present condition of Spot Pond, and its capacity for future supply: —

Boston, Feb. 9, 1893.

The State Board of Health has on several occasions since the spring of 1889 considered applications for advice with regard to additional water supplies for the three communities now using the water of Spot Pond, and in considering these questions the engineers of the Board have given much attention to the probable yield and capacity of this source.

Some figures with regard to the probable condition of this pond during the year 1893 have been made in connection with a recent application for advice from the city of Medford, and as they may be of interest at the present time they are sent to each of you. The data used are the area of the watershed as determined by a reconnaissance upon the ground, sketching the watershed upon the new State map and measuring from it, the storage capacity of the pond as determined from the best maps now in existence; also the records of the yield of the watershed of Sudbury River, which

has been carefully measured by the city of Boston for the past eighteen years.

It has been found by applying these data for many years in the past that the results agree well with the known facts, and they may therefore be looked upon as the best basis at present available for determining what may be expected in the future.

We are informed that the pond on the first day of February was 143.5 inches below high water mark, which, by the tables showing the storage capacity of the pond, would indicate a draught from high water mark down to this level of 731,000,000 gallons.

The following table shows for purposes of comparison the storage in the pond from high water mark down to the present and lower levels.

| Distance below High Water Mark, in Feet. | Storage in Gallons. |
|------------------------------------------|---------------------|
| 11 ft. 11½ in., . . . . .                | 731,000,000         |
| 15 ft., . . . . .                        | 837,000,000         |
| 20 ft., . . . . .                        | 962,000,000         |
| Bottom of pond, . . . . .                | 1,077,000,000       |

In making estimates as to what changes may be expected during the remaining months of 1893, the average consumption is assumed to be 600,000 gallons per day for each community, making a total of 1,800,000 gallons per day. It is found convenient to divide this period into two parts, including in the first one the months of February, March, April and May, during most or all of which the pond may be expected to rise, and in the second the remaining months, when under ordinary conditions it would lower, it is obvious that it is impossible to predict exactly what will happen, but it is fair to assume that the amount of water collected will not be greater than the maximum amount during the past eighteen years, nor will it be less than the minimum amount. It is more likely to be the average amount than any other quantity, but in as important a problem as the water supply of upwards of 50,000 people, provision should be made to avoid a water famine under the most unfavorable conditions which can exist.

It is found that on June first the deficiency of storage (meaning by this term the amount of water that would be required to fill the pond to high water mark) under maximum, average and minimum conditions of yield from February 1 to June 1, 1893, would be as follows : —

*Condition of Spot Pond on June 1, 1893.*

|                          | Deficiency of Storage. |
|--------------------------|------------------------|
| Maximum yield, . . . . . | 331,000,000 gallons.   |
| Average yield, . . . . . | 490,000,000 "          |
| Minimum yield, . . . . . | 677,000,000 "          |

For the period from June 1, 1893, to Jan. 1, 1894, it is obvious that regardless of the height of the pond on June 1 the amount of water going into the pond may be either the maximum, average or minimum, and the following tables show the deficiency in storage on Jan. 1, 1894, under all of these conditions.

(1) Assuming the deficiency in storage on June 1 to be 331,000,000 gallons, the deficiency on Jan. 1, 1894, will be as follows:—

|                          | Deficiency.          |
|--------------------------|----------------------|
| Maximum yield, . . . . . | 172,000,000 gallons. |
| Average yield, . . . . . | 535,000,000 "        |
| Minimum yield, . . . . . | 692,000,000 "        |

(2) Assuming the deficiency in storage on June 1 to be 490,000,000 gallons, the deficiency on Jan. 1, 1894, will be as follows:—

|                          | Deficiency.          |
|--------------------------|----------------------|
| Maximum yield, . . . . . | 319,000,000 gallons. |
| Average yield, . . . . . | 685,000,000 "        |
| Minimum yield, . . . . . | 841,000,000 "        |

(3) Assuming the deficiency in storage on June 1 to be 677,000,000 gallons, the deficiency on Jan. 1, 1894, will be as follows:—

|                          | Deficiency.          |
|--------------------------|----------------------|
| Maximum yield, . . . . . | 494,000,000 gallons. |
| Average yield, . . . . . | 863,000,000 "        |
| Minimum yield, . . . . . | 1,018,000,000 "      |

The most important conclusions to be drawn from the tables are, first, that with the average conditions from now until next January the pond will be at substantially the same level as at the same time this year; second, that if either one of the periods into which the year has been divided furnishes the average quantity of water and the other furnishes the minimum quantity, the water in the pond will be reduced to the 15-foot mark; and lastly, that if the yield for both of these periods should be a minimum the pond will be drawn practically to the bottom.

All of these estimates are based upon an average draught of 1,800,000 gallons daily from the pond, but it is doubtful if the draught can be kept as low as this without supplementary supplies

to furnish a portion of the water used. It is probable that a larger draught than the amount above given has had an influence in lowering the pond during the past year. The net loss of storage from the pond from Feb. 1, 1892, to Feb. 1, 1893, was 338,000,000 gallons. The same loss in the next twelve months would take all of the water out of the pond.

Not only should the conditions for the remainder of the present year be considered but the conditions which will exist subsequently until the time when a permanent supply is introduced should be considered, and it is therefore of the utmost importance that measures should be taken immediately, by providing supplementary sources or by making arrangements with some community which has water to spare, to get as much water into the pond as possible, or, what is the same thing, to take less water from the pond so as to have a larger supply in the pond to provide for the future contingencies, such as a rapidly growing population and supplementary supplies which may become unsuitable for domestic use. Every million gallons of water which can be added to the pond has a distinct value to the three communities now depending upon this source, which is much in excess of the mere cost of pumping the water, and it would be a benefit to all of the communities if a fixed price were made per million gallons of water, which should be charged to each community drawing more than a certain defined quantity and credited to any community taking from the pond less than this amount. This would offer an incentive for individual action on the part of those places which now have or can provide supplementary sources of supply and would not be unjust to any town that may be unable to obtain a supplementary source, as this town would only pay to the others what it would save in the cost of constructing and maintaining a pumping plant.

**MEDFORD.** The water commissioners of Medford applied to the Board, Jan. 4, 1893, for its advice relative to taking an additional water supply from wells west of Forest Street in Medford. The Board replied as follows:—

BOSTON, Feb. 2, 1893.

The State Board of Health has considered your application in regard to an additional water supply to be taken from driven wells in the flat open land west of Forest Street, where test wells have already been driven.

The Board has caused analyses to be made of samples of water taken from these wells and finds that it is a water which has at

some time been polluted, but which has been very thoroughly purified by its passage through the ground. The water as it now comes from the ground would be entirely satisfactory to the consumers as a drinking water, but it is much harder than the Spot Pond water and therefore would not be as good for washing purposes and for use in boilers. The hardness of the water, however, is not as great as that of several water supplies which are now in use in this State, and if the quality of the water remains as at present it would be satisfactory for the purposes of a public water supply. The situation of the test wells, however, is such that it seems probable that when a continuous draft is made upon the ground the water will be drawn in part from the territory south of the wells where there is a large population, and the water will become harder than it is at present, and it may be less perfectly purified; moreover, even if a large tract of land is purchased and controlled by the city for the protection of a water supply at this place the growth of the city will undoubtedly cause a material increase of population upon adjacent land, which contributes a portion of the water to supply the wells, and the character of the water may be further unfavorably affected in this way.

The Board would not therefore advise the construction of works for taking a permanent supply from this place, but in view of the necessity for supplementing the supply from Spot Pond, advises that this is a suitable source from which to obtain a temporary supply. The quantity of water to be obtained from this source is, with the present information, somewhat indefinite. It seems very doubtful if the source can be depended upon to furnish more than from 250,000 to 400,000 gallons per day continuously, though it is not impossible that during the wetter portions of the year a considerably larger quantity of water might be obtained.

In addition to the driven wells there is another source from which a temporary supply might be obtained, viz., the stream which flows just west of Forest Street, below where Elm Street joins it. Above this point there are very few houses or other sources of pollution upon the watershed, the area of which as measured from the State map is 0.58 square mile. An analysis of the water recently made shows that it is at the present time of suitable quality for water supply purposes, except that before being pumped it should be stored in a reservoir sufficiently large to permit the floating particles which are almost always found in brook waters to settle. During several months of an ordinary year the flow of this stream should be as high as 600,000 gallons per day, and during two months or more of such a year it should range from one to two million gallons per day. This source has the advantage that

it is very near the main pipe which leads to the town, and the water would have to be lifted to a less height to force it into the main. It is obvious, however, that in order to make it of value in the present emergency the works should be constructed at once so as to take advantage of the larger amount of water which flows in the spring of the year, as the amount of water to be obtained from this source in the summer would be comparatively small. The water would also be soft and suitable for laundry and boiler purposes, though not as palatable as that taken from the ground.

The choice of these two sources or whether both of them shall be utilized is a question which is left for your decision. The Board, however, considers it imperative that a supplementary supply or supplies should be provided at once by the communities using the water of Spot Pond in order to avoid a water famine during the next autumn and winter.

The results of certain computations with regard to the future condition of Spot Pond and a suggestion as to measures which should be taken to prevent the supply from being exhausted are embodied in another communication, a copy of which will be sent to you and to the water boards of Malden and Melrose. (See pages 28-31, preceding.)

**MELROSE.** The committee on additional water supply of Melrose applied to the State Board of Health, Dec. 5, 1892, for its advice as to the propriety of taking, either alone or in conjunction with Malden and Medford, the waters of Great Pond, in North Andover, together with Mosquito Brook and Boston Brook in the same town, as additional sources of water supply. The Board replied to this application as follows:—

Boston, Jan. 16, 1893.

In your application of Dec. 5, 1892, giving notice of your intention to provide an additional water supply for the town of Melrose and asking the advice of the Board in regard thereto, you make the following statement: "The plan proposed is, alone or in conjunction with the cities of Malden and Medford or either of them, to obtain authority from the Legislature to take and hold the waters of Great Pond in North Andover, and to acquire by purchase or otherwise the waters of Mosquito Brook and Boston Brook in said town of North Andover."

The State Board of Health has up to the present time received no applications relating to these sources from the cities of Malden or Medford and therefore considers only the first alternative, viz., a supply for Melrose alone.

Great Pond only has been investigated by the Board up to the present time, and it is found from this investigation and analyses of the water of the pond that the water is of satisfactory quality for all the purposes of a public water supply and that the quantity of water which the pond will furnish will be more than sufficient for the probable population of Melrose for the next thirty years.

Owing to the fact that the pond is situated wholly within the town of North Andover the Board is of opinion that this town has a primary right to so much of the water of the pond as is necessary to supply its inhabitants with water.

With regard to the appropriateness of this source for a water supply for the town of Melrose, the Board thinks it highly probable that a sufficient supply of good water for the town can be obtained at a less distance than sixteen miles and with less expense; and for this reason, and having regard for the interests of other communities much nearer Great Pond, which may in the future need its waters as a source of water supply, the Board advises the town to make examinations of nearer sources, and until such examinations are made is unable to advise that this is the most appropriate source of supply for the town of Melrose.

The Board will investigate the other sources mentioned in your application and advise you with regard to them as soon as practicable.

On February 3 the Board transmitted the following further communication upon the same subject to the committee on additional water supply of Melrose: —

Boston, Feb. 3, 1893.

The State Board of Health in its communication of Jan. 16, 1893, to your committee, relating to an additional supply of water for your town from Great Pond in North Andover, stated that further advice would be given with regard to the other sources mentioned in your application, viz., Mosquito and Boston brooks.

The application apparently relates to so much of these brooks as lies within the limits of the town of North Andover. The areas of the watersheds of these brooks above the points where they cross the town boundary, as measured from the topographical map of the State, are respectively 7.51 and 6.36 square miles, and their distances at these points in an air line from Melrose are  $14\frac{1}{2}$  and  $12\frac{1}{2}$  miles. These watersheds have been examined upon the map above mentioned, and upon the ground by one of the engineers of the Board, and they were not found to have any special characteristics which would make them as a whole particularly appropriate as sources of supply for Melrose or as desirable as other watersheds nearer the town.

It has been learned from statements made by a member of your committee and by your engineer, that it is proposed to utilize only so much of the upper end of these brooks as can be diverted by gravity through a ditch or canal along the side hill into Great Pond. In this case the area of watershed to be utilized is, according to the map above mentioned, in the neighborhood of three square miles instead of the total of about fourteen square miles above the town boundary. The three square miles are sparsely populated so that there is little danger that the water will be polluted, but there are swampy areas which give the water of the larger (Boston) brook a high color which would be objectionable if the water was to be taken directly into the pipes. If, however, this water is diverted as proposed into Great Pond its color will nearly disappear by long storage and by mingling with the nearly colorless water naturally in the pond.

The Board is of opinion that the town should not seek to acquire rights to the whole of Mosquito and Boston brooks within the town of North Andover, as the portions not available for diversion into Great Pond may be needed in connection with water supplies from the Ipswich Valley for other places in the eastern part of the State. If, however, the town of Melrose should be granted the right to take the waters of Great Pond it is appropriate that it should also be granted those portions of Mosquito and Boston brooks which can be diverted by gravity into it.

The water board of Melrose applied to the State Board of Health May 16, for its advice as to taking an additional water supply from wells to be driven in the meadow upon the north side of Ell Pond, and on July 5, the committee on additional water supply applied for advice with reference to taking water from other sources. The Board replied to these applications as follows:—

Boston, Aug. 10, 1893.

The State Board of Health received from the Melrose water board on May 16, 1893, an application for its advice relative to a proposed additional system of water supply to be taken from the ground on the north side of Ell Pond. On July 5 a second application was received from the committee on additional water supply for advice relative to taking a supply from Martin's Meadows, so-called, from Bennett's Pond or Meadows and from the Wakefield Water Company. On July 5 the last mentioned application was amended by adding Long Pond and its immediate vicinity to the sources before mentioned.

Before considering these sources in detail it will be well to refer in a general way to the capacity of your present source of supply, Spot Pond, and to the needs of your town.

Spot Pond during a year of average rainfall will supply to each of the communities taking water from it about 630,000 gallons of water per day; and, during a series of dry years, such as have occurred in the past, will furnish about 500,000 gallons per day to each community without falling to a lower level than it reached in February, 1893. With the pond at its present low level it cannot be depended upon to furnish even 500,000 gallons per day to each community if the next two or three years should be unusually dry. The consumption of water in Melrose by the meter records from September, 1892, to June, 1893, inclusive, averaged 565,000 gallons per day, which is 65,000 gallons in excess of the safe capacity of the pond for a series of dry years, even assuming it to have been filled in the spring, and still more in excess of its capacity in its present low condition. It is obvious, therefore, that to meet even the requirements of the present and the very near future it will be necessary to provide an additional source of supply or to decrease the consumption of water.

The consumption of water in Melrose at the present time is about 57 gallons per inhabitant, which is more than the amount used by most towns similarly situated. As instances of low consumption per inhabitant may be mentioned: Brockton, 25 gallons; Middleborough, 26 gallons; North Attleborough, 26 gallons, and Fall River, 26 gallons. On the other hand, Beverly uses 70 gallons, Braintree 62 gallons, and Brookline 80 gallons. During the period from September, 1892, to June, 1893, inclusive, Malden used 50 gallons and Medford 48 gallons per inhabitant.

It seems highly desirable that Melrose should take energetic measures to restrict waste, but in view of the fact that the present demands upon Spot Pond so largely exceed its capacity, and having regard to the present low state of the pond and the greater demand for water from year to year, due to the increasing population, the Board is of opinion that a further supply should be obtained without delay.

The great expense to which Melrose would be subjected if it should attempt to obtain by itself a permanent supply of water, which can only be had from a comparatively great distance, the fact that the Legislature has already directed that investigations be made with a view to obtaining a water supply for Boston and its suburbs, and the need of an immediate addition to the present supply, all lead to the conclusion that it is wise to obtain at a comparatively small cost a temporary supply which will meet the

requirements for the next five or six years. Should any of the sources mentioned by your committee be adopted, they should be considered merely as temporary sources which will have to be abandoned whenever the quality of the water becomes impaired by the growth of population upon the territory from which the supply is derived or by other causes, or whenever a more satisfactory and permanent water supply is introduced.

Of the sources mentioned by the committee it may be said that the water of Bennett's Pond, if taken directly from the pond, would not be of suitable quality on account of the large population near the upper portion of the brook which feeds it. With regard to a ground water from the vicinity of Bennett's Pond, no definite answer can be given because no investigations of the ground at this place have been made. It is not improbable that the quality of the water would be good, but, judging from the surface indications, this source could hardly be expected to furnish a sufficient quantity of water to make it a desirable one to adopt at the present time.

Long Pond by itself would not furnish a sufficient quantity of water to warrant taking an additional supply from it, and if a stream which flows near its westerly end should be diverted into it the quality of the water would not be satisfactory if taken directly from the pond. With regard to obtaining a ground water supply in this vicinity no investigations of the ground have been made, but, judging from surface appearances, the conditions are even less favorable than in the vicinity of Bennett's Pond.

The Wakefield Water Company now takes its supply from Crystal Lake, and the water is of suitable quality for the purposes of a public water supply. The quantity of water which this source will furnish in a series of dry years is but little, if any, in excess of the present requirements of the two towns now supplied by the Wakefield Water Company, and the only water which this company has to spare is the excess, during years of average or high rainfall, above the requirements of the two towns now supplied. The Board, therefore, does not advise the town of Melrose to depend upon the Wakefield Water Company for its additional supply. On the other hand, it is extremely important as a precaution against a water famine in the next few years that Spot Pond should be again filled, a result which can be accomplished if each of the communities now drawing water from the pond should obtain the greater part of its supply from some other source or sources; and it may therefore be desirable, if suitable arrangements can be made, to have the Wakefield Water Company supply as much water to Melrose as the capacity of its source will permit.

A sample of water collected from Whittier's wells in Martin's Meadows, so-called, on July 20 showed that the water obtained from the ground at this place was of satisfactory quality for the purposes of a public water supply, and from an examination of the premises it seems probable that this water will remain of suitable quality for use, at least until there is a further increase of population in this vicinity. The quantity of water which this source will furnish is apparently limited, and it is extremely doubtful if it alone will furnish a sufficient additional water supply for the town. Samples were also received from wells in the meadow above the one already mentioned, but the water from these wells was not of satisfactory quality to pump directly into the pipes.

The territory just north of Ell Pond has been tested in several places. The first test was made in January, 1893, by pumping from a line of driven wells very near the pond. This test lasted for fifteen days and the average quantity of water pumped is said to have been about 461,000 gallons per day. Three samples of water from these wells were sent to this Board for analysis. One was taken at the beginning of the test, another a week later, and the third at the end of the test. All of these samples were clear and colorless and free from odor, and, although they all showed, by the greater amount of mineral matter and hardness than the natural waters of this region, the effect of the population upon the territory from which the supply is derived, the analyses also show that the water had been very thoroughly purified by its passage through the ground.

Three additional samples taken from this vicinity in June and July, 1893, gave results which confirmed those above mentioned, the analyses showing that in every case the water had been completely purified, chemically, by its passage through the ground. The wells from which two of these last mentioned samples were taken were 175 feet from the pond, while the third sample was taken from one of the line of wells near the pond. A bacterial examination of a sample of water from one of these wells showed that the water was of good quality, bacterially.

There seems to be no doubt that the quantity of water which can be obtained from the ground in this vicinity is greater than from any of the other sources mentioned, and the principal question which arises with regard to this source is as to whether the water will remain of suitable quality for use after long-continued pumping. The principal source of danger is that the water of the pond, which is highly polluted, will find its way through the ground to the wells without being thoroughly purified by filtration. Ex-

perience has shown in some cases that water may filter from a pond to wells or to a filter-gallery and under some conditions be thoroughly purified by its passage through the ground, and yet under other conditions fail to be purified. It is impracticable to predict in the present case whether the water drawn from the ground will deteriorate in quality from this cause. Taking into account, however, the urgent needs of your town and the difficulty of obtaining a sufficient quantity of water from a better source, the Board would advise that this location be adopted as a source of supply, but with the understanding that the works are to be of a temporary character and that the water is to be analyzed frequently and its use discontinued if it should become impure. The wells should be located not less than 175 feet from the pond and further from it if practicable.

On Feb. 9, 1893, the Board sent a communication to the water boards of the three places drawing water from Spot Pond; and, after giving the results of estimates as to changes in the level of the pond which would be likely to occur under varying conditions of rainfall, the Board ended its communication with the following statement, to which it would again call attention:—

It is of the utmost importance . . . to get as much water into Spot Pond as possible, or, what is the same thing, to take less water from the pond so as to have a larger supply in the pond to provide for future contingencies, such as a growing population and supplementary supplies which may become unsuitable for domestic use. Every million of gallons of water which can be added to the pond has a distinct value to the three communities now depending upon this source, which is much in excess of the mere cost of pumping the water, and it would be a benefit to all of the communities if a fixed price were made per million gallons of water, which should be charged to each community drawing more than a certain defined quantity and credited to any community taking from the pond less than this amount. This would offer an incentive for individual action on the part of those places which now have or can provide supplementary sources of supply, and would not be unjust to any town that may be unable to obtain a supplementary source, as this town would only pay to the others what it would save in the cost of constructing and maintaining a pumping plant.

**MENDON.** The selectmen of Mendon applied to the Board, Dec. 27, 1893, for its advice relative to taking the water of Mendon Pond as a public water supply. The Board replied to this application as follows:—

BOSTON, Jan. 5, 1894.

The Board has already considered the question of the use of this pond as a source of water supply, in response to an application

made by the town of Uxbridge in 1892, and has caused analyses of the water to be made in October, 1892, and every month from May to November, 1893. During all of this time the water has been of satisfactory quality for all the purposes of a public water supply, and there seems to be no reason to doubt that if it is protected from pollution it will continue to be of satisfactory quality in the future.

Owing to its situation near the village of Mendon it is an appropriate source from which to take a supply of water for the village and any part of the town to which it may be desirable to extend the pipes.

The amount of water required for the supply of Mendon will not be large, and in the opinion of the Board the use of the pond as a source of water supply for Mendon should not prevent its use as a source of water supply by Uxbridge.

**METHUEN.** The water commissioners of Methuen applied to the Board, April 13, 1893, for advice as to obtaining a water supply for the town from driven wells near Sargent's Brook in the east part of the town. The Board replied as follows:—

Boston, May 19, 1893.

The State Board of Health has considered your application of April 13, 1893, relative to a proposed water supply for the town, to be taken from driven wells near Sargent's Brook, and has caused examinations of the premises and analyses of the water to be made.

The analysis of a sample of water sent in from one of the flowing wells showed the water to be very pure and soft, and in all respects an excellent water for the purposes of a public water supply. After pumping for nearly six days, however, from these wells another sample was collected, and the character of the water was found to have undergone a decided change and to be much less satisfactory. Should this deterioration continue with steady pumping, as has been the case in some other places in the State, the water would become objectionable.

The watershed above the point where the wells are located was examined and its area determined approximately by sketching its outlines upon the topographical map of the State, and subsequently measuring it. This area was found to be so small that the total amount of water flowing from it, through the brook and through the ground, in a dry year would not be in excess of the requirements of a water supply for Methuen, having due regard to future

needs. It was obvious from an examination of the watershed that much of the water would flow off through the brook, particularly in the spring of the year, so that the supply to be obtained from the ground would be much less than the total flow from the watershed, and probably not enough during the dryer portions of a dry year to supply the town as soon as water is generally introduced.

On July 5 the water commissioners of Methuen again applied to the Board for its advice upon the question of taking a water supply for the town from wells driven near the Spicket River at the junction of the brook leading from Harris Pond. The Board replied to this application as follows : —

Boston, July 25, 1893.

In response to your application of July 5, 1893, with regard to a proposed water supply for the town of Methuen, to be taken from driven wells located near the Spicket River near the point where it is joined by the brook leading from Harris Pond, the Board has caused an examination of the locality and an analysis of a sample of water sent in by you from one of these wells to be made. The analysis showed that the water sent in was of excellent quality for the purposes of a public water supply. Judging from the tests made under your direction, and from an examination of the territory in the vicinity of the test wells, it is probable that a sufficient supply for the town for at least a few years may be obtained from the ground near where the tests have been made, and this location has the great advantage that it is well situated for taking a supplementary supply of water from Harris Pond whenever the quantity of water which can be obtained from the ground proves insufficient.

NEWBURYPORT. In the report of the State Board of Health to the Legislature, dated Jan. 10, 1893 (Senate Document 4, 1893), it was stated that the water of the Merrimack River had been furnished directly to the citizens of Newburyport by the Newburyport Water Company, and that a letter had been sent to the Newburyport Water Company, November 3, informing them that the water of the Merrimack River was unfit for domestic use, and advising them to obtain a further supply of pure water without delay. This advice having been disregarded by the company, an epidemic of typhoid fever took place in January and February, 1893, among the citizens of Newburyport. The Board then ad-

addressed the following communication to the mayor of Newburyport : —

BOSTON, March 3, 1893.

*To the Mayor of Newburyport.*

DEAR SIR : — On the 3d of November, 1892, having learned that the Newburyport Water Company had at times pumped the water of the Merrimack River and distributed it to the citizens of Newburyport, the State Board of Health addressed the following letter to the company : —

The Board, as a result of extended examinations of the effect of using the Merrimack River water at Lowell and Lawrence, reached the conclusion that it is to this cause that the excessive mortality from typhoid fever in these cities, as well as the very severe epidemic of this disease in the winter of 1890-91, may be ascribed. The condition of this river at Newburyport is worse than at either Lowell or Lawrence, owing to the added sewage of the cities of Lawrence and Haverhill, and the town of Amesbury.

In view of this condition of affairs, the Board is of opinion that the Newburyport Water Company should obtain a further supply of pure water without delay, so that there will be no further occasion for pumping water directly from the river.

In the Twenty-second Annual Report of this Board, page 527, it was shown that the introduction of a pure water supply into Newburyport in 1881 was followed by a reduction in the death-rate from typhoid fever of more than one-half.

It now appears from an investigation recently made by this Board that the frequent pumping of a considerable quantity of the water of the river has been followed very closely by an epidemic of typhoid fever among your citizens. This epidemic, in the opinion of the Board, is due to the use of the river water, following an increased prevalence at places higher up the stream.

These results emphasize still more strongly the opinion of the Board expressed in its letter of November last to the Newburyport Water Company, relative to the necessity of "obtaining a further supply of pure water without delay," and in the opinion of the Board such a supply cannot be obtained by developing the present spring-water sources.

The mayor of Newburyport applied to the State Board of Health, April 13, 1893, for advice as to taking the water of Artichoke River, in that city and the town of West Newbury, as a source of water supply for the city, such water to be purified either by artificial or natural filtration through sand. The Board replied as follows : —

BOSTON, April 24, 1893.

An examination of this source shows that by the construction of a storage reservoir as proposed it can be made to furnish a sufficient quantity of water for the city of Newburyport for a long time in the future. With regard to the quality of the water the examinations thus far made show it to be a water of fair quality, but it would not probably be satisfactory for drinking purposes without filtration. The Board is of opinion that it will be feasible to so filter this water that in connection with the existing works, or independent of them, an ample and satisfactory supply for the city can be obtained.

The Board makes a reply at this time instead of waiting for your further surveys and investigations because it understands that its advice is desired now in connection with pending legislation, and will advise you further with regard to the filtration of the water when the results of the further surveys and investigations are presented.

**NORTH ANDOVER.** The committee on water supply of the town of North Andover applied to the Board, Dec. 13, 1892, for advice relative to taking the water of Great Pond in that town for a public water supply. The Board replied to this application as follows:—

BOSTON, Jan. 16, 1892.

The State Board of Health has considered your application dated Dec. 14, 1892, with regard to a proposed water supply for the town of North Andover, to be taken from Great Pond within said town.

The Board has caused examinations of the pond and analyses of its water to be made, and finds that the water is of satisfactory quality for all the purposes of a public water supply and that the quantity of water which the pond will furnish is many times in excess of the quantity which will be required for the supply of the town.

The Board is therefore of opinion that Great Pond in North Andover is an appropriate source from which to take a water supply for the town.

**PEABODY.** The Water Board of the town of Peabody sent the following communication to the State Board of Health, April 18, 1893, relative to the threatened pollution of their water supply by drainage from new settlements upon the immediate watersheds of the two ponds used as water supplies:—

PEABODY, MASS., April 18, 1893.

*State Board of Health, Boston, Mass.*

GENTLEMEN:—By a vote of the water board, I am instructed to respectfully represent to you a matter of vital importance to the town of Peabody. Parties have purchased the land north of Spring and Brown's ponds, the water supply of the town, and have cut it up into house lots, and as the land on both places slopes toward the ponds, the matter of polluting the water in the ponds is deemed of such great importance to the town that the Water Board would respectfully request that a member of the State Board of Health come here some time to look over the premises, and suggest some remedy, if possible.

Yours respectfully,

HENRY BAETJE,

*Clerk, Water Board.*

In compliance with this request of the water board of Peabody, the secretary of the State Board visited the sources of water supply of the town, in company with the water board, and afterward addressed a letter to them, by instructions of the State Board of Health, giving such information as to existing statutes as would be serviceable for the protection of their water supplies from pollution.

ROCKPORT. An application was received from H. N. Woods and others, and the selectmen of Rockport, Jan. 4, 1893, asking the advice of the Board relative to the taking of a public water supply from Cape Pond, or Mill Pond Brook in that town, and in the event of these sources proving unsuitable, from the Gloucester Water Company. The Board replied as follows:—

BOSTON, Feb. 18, 1893.

An application with regard to Cape Pond as a source of water supply for Rockport was made to the Board on March 18, 1890, and the reply of the Board dated March 26, 1890, was as follows:—

The Board has caused samples of water to be taken from the pond and has had them submitted to chemical and microscopical examination. The water at the present time is not found by either examination to be of satisfactory quality. It contained an unusually large number of organisms, and is therefore specially liable to bad tastes and odors, such as have affected many water supplies in the State. It is also shown by analysis to contain a large amount of ammonia, which indicates the presence of decaying matter. It is not feasible to tell whether the water

at the present time is better or worse than at other seasons of the year; but, as a rule, the quality of the water of ponds is worse in the summer.

In view of this unsatisfactory condition of the water, the Board cannot at the present time advise that this pond will be a desirable source of supply for the town of Rockport, unless the water supplied is first efficiently filtered. If it should be found by subsequent examinations that the water of this pond is better at other seasons of the year than at the present time, the Board might have occasion to modify the advice above given.

Since the above date four samples of water were collected from the pond, in August and October, 1892, which showed by the chemical examination the presence of more organic matter than is desirable in water, and by the microscopical examination the presence of a large variety and number of organisms. On the whole, however, these samples indicated that the water was of better quality than in 1890. A sample collected in February, 1893, shows still less organic matter and fewer organisms, so that the water as represented by the last sample may be considered as of satisfactory quality for water supply purposes. Notwithstanding these changes for the better in the organic matters in the water, the mineral contents show that there is an increasing pollution of the pond by the waste matters which come from the glue factory upon the watershed, and there is little doubt that if these waste matters continue to affect the pond the water will be specially liable to bad tastes and odors caused by too great an amount of organic matter and too many organisms in the water, whereas if the waste matters were removed from the watershed so that they could not affect the pond by direct flow into it, or by filtration through the ground, the quality of the water would probably improve to a considerable extent in two or three years, and after a longer term of years the water in the pond would resume its natural character.

The Board is therefore of opinion that this pond should not be used for water supply purposes unless the pollution of its water ceases, but that if the pollution is stopped the water will become of satisfactory quality for the supply of the town.

With regard to the quantity of water which this pond will furnish, it will probably supply sufficient water for the present population of the town but not enough to provide for a growth of population, and in designing works for taking a supply it would be well to take into account the need of an additional supply, which can probably be obtained from the streams which come from a northerly direction into the brook which flows from Cape Pond, or possibly from wells in the low land through which this brook flows.

Millpond Brook, so-called, is naturally inferior to Cape Pond as a source of water supply for Rockport, and it is very doubtful if it could be made to furnish a sufficient quantity of water for even the present population.

**SALEM.** The water commissioners of Salem applied to the State Board of Health, Feb. 17, 1893, for advice relative to increasing the present water supply of the city by taking water from Beaver and Norwood's ponds and Longham Meadow, certain regions which are tributary to Miles River, and conveying the same by a canal to Wenham Lake, the present source of supply. The Board replied as follows:—

BOSTON, April 4, 1893.

Investigations of the present source of water supply for Salem and Beverly (Wenham Lake) show that the safe capacity of this source has been exceeded to a considerable extent, and that a new supply should be provided by the end of 1893 if not before. The most economical source from which to obtain such a supply is that referred to in the application, as these brooks, at the point where their waters can be diverted, are only about half a mile from Wenham Lake, and so few feet below its level that the water can be diverted into the lake without pumping by raising the water of the brooks by means of a low dam.

Since your application was made two sets of analyses of water from these brooks have been made. The first one was made on March 1st, when there was a large amount of snow on the ground and very little water running in the streams. At this time the water was very dark-colored and had a disagreeable odor and taste, so that it would be wholly unsatisfactory as a source of water supply if taken directly into the pipes. The next sample was taken on March 15th when a large part of the snow had melted and a great amount of water was flowing in the streams. The water of the Longham Meadow Brook at this time, although somewhat turbid, owing to the presence of earthy matter, had only one-third as much color as on March 1st and was in other respects a much better water. The water of the brook flowing from Norwood's Pond also showed a very decided improvement, but not as much as in the other case, as the water from the melting snow had not had time to crowd out all the water previously in the ponds on this stream.

If the water of these streams was turned into Wenham Lake near its outlet, as is now proposed, it would mingle with the water

of the lake, making a mixture very much better than the water coming from the brooks, and, in addition, the water standing for so long a time before being used as it would in so large a body of water as Wenham Lake would improve to a very considerable extent by bleaching and sedimentation. In order, however, to maintain as nearly as possible the present standard of Wenham Lake water, it is highly desirable that only so much water as may be necessary should be turned into the lake from these brooks, and that it should be turned in at the season of the year when the water in the brooks is in its best condition.

The stream at the proposed point of diversion is as before indicated lower than the lake; and, in order to divert the water into the lake by gravity, it is necessary to raise the water in the stream by means of a dam. The question has therefore been raised as to whether it is not best to make a dam high enough to form a large reservoir which will furnish a valuable addition to the present storage capacity. The surveys of this reservoir have not yet been completed and it is not feasible to tell from observation alone what its character will be. It seems probable, however, that unless a very large amount of money is spent in its preparation the water would deteriorate to a very considerable extent by standing in it and that, at the present time, it would be better to construct a dam having only sufficient height to turn the water into the lake. Even a low dam at this place will flow the water back for a long distance up the valley of the Longham Meadow Brook, and if the reservoir is to be kept filled at all seasons of the year it should be prepared to receive this water by the removal of all soil and vegetable matter and the deepening or filling of the shallower portions. If, however, the reservoir should be filled to divert water into the lake only in the winter and spring it is not improbable that satisfactory results may be obtained by a less expensive preparation.

It may be feasible by ditching or otherwise draining the swampy lands or ponds upon the watersheds of these brooks to greatly improve the quality of the water flowing in them, and the Board would advise that this question of the improvement of these sources should be investigated and that any act authorizing the taking of these sources should contain such provisions as will permit this work to be done.

The total area drained by these streams is much larger than that now supplying Wenham Lake, and, in connection with Wenham Lake and its watershed, should furnish a supply of water for Salem and Beverly for a long time in the future without building a large storage reservoir, provided the water is economically used.

The amount of water now consumed by Salem and Beverly, as given in the annual reports of the water boards, is unusually large for such communities, and the Board would therefore advise that measures should be taken to restrict the waste of water ; not, however, with the expectation that the need of an additional supply can be avoided, but rather with a view to maintaining as nearly as possible the present standard of quality of the water supply by adding to it as little water from the new sources as possible, and also with a view to making the proposed addition provide for as far in the future as possible.

Taking everything into consideration the Board is of opinion that the two streams mentioned in your application, including with them a small portion of the main stream below their confluence, are the most appropriate sources for obtaining an additional water supply for Salem and Beverly.

The Board has given its present views in a general way as to the best method of obtaining such a supply from these sources, but will advise you more in detail when you have made a further study of the subject and can present more definite plans.

**SAUNDERSVILLE.** The treasurer of the Saunders Cotton Mills in Grafton, applied to the Board, October 18, for advice as to supplying the mill and houses in its neighborhood with water from springs upon a hill near the village. The Board replied as follows : —

Boston, Nov. 2, 1893.

The Board has caused an analysis of the water from one of these springs, and an examination of the territory from which they derive their supply, to be made. The water is very soft and of suitable quality for all the purposes of a water supply, and the covering which you propose to put on the reservoir will tend to preserve the good quality of the water when it is stored. In order to maintain the purity of the spring water, care should be taken to exclude all surface water.

Judging from the quantity of water discharging from the springs at the time the examination was made by the engineer of the Board, and from statements made to him as to the permanence of these springs, it seems probable that they will furnish enough water to make them a valuable source of supply for the mill and the houses in its vicinity.

In addition to the sample of water from the spring, another sample, taken from a well which now supplies water to the mill, was analyzed. This analysis shows that a portion of the water

coming to this well has at some time been polluted and afterwards thoroughly purified by its passage through the ground to the well. While there is no reason to think that this water, in its present condition, would be injurious to the health of those drinking it, it is a much less desirable source of domestic supply than the springs on the hill.

**SCITUATE.** M. R. Simmons and others, and the selectmen of Scituate applied to the Board, Dec. 10, 1892, for its advice relative to taking water for supplying the village of Scituate Harbor, from the valley of Satuit Brook in that village. The Board replied as follows:—

Boston, Feb. 21, 1893.

The general outlook for obtaining a sufficient quantity of water for present and future requirements from the ground where the test wells are located is favorable both as regards the area and topography of the watershed from which the supply would come, and because the test wells show the presence of a layer of porous sand from which water can be drawn. The amount of water to be obtained, however, will depend upon the extent of this porous layer, and the freedom with which water can be pumped from it, and it will be advisable to make some further tests to determine these features before constructing works.

The sample of water collected from a flowing test well is of good quality, and it seems probable that the quality of the water will remain good when a supply is pumped from the ground. In some cases, however, the quality of water from wells in a meadow deteriorates when pumped, and it would be well to have additional samples analyzed when a pumping test is made.

**SHARON.** The board of health of Sharon, under instructions from the town, requested the advice of the State Board of Health, Aug. 28, 1893, with reference to the possible pollution of the public water supply of the town, under existing conditions, and as to the best practicable method of assuring its purity in the future. The Board replied as follows:—

Boston, Oct. 6, 1893.

When any part of the territory from which a well derives its supply is populated and the waste waters of this population are discharged into the ground, these waters percolate downwards until they reach the level of the water in the ground, and then, mingling with the natural ground water, filter slowly toward the well. In

such a case the dissolved mineral matters (for instance, common salt, and the salts of lime and magnesia which make water hard) are not removed by the filtration; but the organic matters may be decomposed and wholly transformed into harmless mineral matters by filtering through the ground for a sufficient distance.

The State Board of Health has caused chemical analyses of water from the well of the Sharon Water Company to be made from time to time since June, 1887, the last analysis being made in September, 1893. These analyses show the presence in the water of some of the mineral matters due to the population upon the territory from which water filters toward the well, and the water, although not hard, is harder than it would be if it were not for the population upon this territory. They also show that such polluted waters as have mingled with the ground water have been very thoroughly purified at all times, and the recent analysis fails to reveal even a trace of organic matter. It may therefore be said that the water is very pure at the present time.

There is scarcely a doubt that the waste waters discharged into the ground from the more distant points will continue to be thoroughly purified before reaching the well, and the effect of an increase in population at these points would be to increase the hardness of the water rather than to render it injurious to health. There is a greater probability that the water may at some time be polluted by the wastes which enter the ground at nearer points, say within a distance of from 600 to 800 feet from the well; and it is highly desirable that within this distance this method of disposing of the waste matters shall cease.

If there should be a very large increase of population upon the more distant territory which contributes water to the well, it may be necessary at some time in the future to provide a water-tight system of sewers to carry off the liquid wastes, or to obtain the water supply from some new location.

**SOUTHBRIDGE.** The Southbridge Water Supply Company applied to the Board for its advice, Sept. 5, 1893, relative to the question of increasing the public water supply by building a new dam about one mile south of the present upper reservoir, and as to the improvement of the present supply and storage capacity. The Board replied as follows:—

Boston, Oct. 13, 1893.

We are informed by your engineer that this new reservoir will have sufficient capacity to store 50,000,000 gallons; but, as you

have not made surveys of the watershed, to determine its area, it is not feasible to advise you other than in a general way as to the quantity of water which this source will furnish.

It is also the case that when this source was inspected by an engineer of the Board, there was no water running in the stream at the site of the proposed dam, so that it was not possible to get a sample of water for analysis. The inspection of the watershed by this engineer, however, indicated that the water flowing from it was naturally of good quality, and that more water could probably be obtained from this source than from the present works.

The water would probably deteriorate somewhat by storage in this large reservoir, in any case; but much more if the reservoir is not cleaned, than if it is thoroughly cleaned by the removal of all soil and vegetable matter.

In answer to your second question asking the advice of the Board with regard to the improvement of the present supply, it may be said that it does not appear feasible to increase the storage in a satisfactory manner nor to materially increase the quantity in any other way. It should also be borne in mind that if you adopt the new source and construct the large proposed reservoir upon it, it will be feasible to operate the two systems together so as to utilize some of the water which now flows to waste over the lower dam of your present works in the spring of the year. For example, when enough additional water takers have been connected with the works to use all of the water which the present and proposed works will furnish in a dry time, it may frequently happen that the lower reservoir will be overflowing, while the proposed reservoir, owing to its large size, will not be full. At such times it will be feasible to supply the greater part of the town from the old source, thereby permitting less of the water to flow to waste, and reserving the water of the proposed reservoir for use during the drier portions of the year.

With regard to the improvement of the quality of the present supply, the measures suggested are the removal of any organic matter which may be in the reservoir, and the ditching of any lands of a swampy nature over or through which the streams flow to the reservoirs, so as to prevent, as far as possible, the water from coming into contact with organic matter or standing upon the surface of these lands.

It is improbable that your present and proposed works together will furnish as much water as ought to be provided for a large and growing town like Southbridge, and the Board would therefore advise that you have thorough investigations made with a view to determining the best source for the permanent supply of the town.

Should you find a source which will furnish an adequate supply of good water it would probably be a measure of true economy to adopt it at once, rather than to spend money upon a source which in a very few years is likely to prove inadequate, if the pipe system of the town should be extended to any considerable extent. Should your investigations of the larger sources lead you to conclude that it is desirable to adopt one of them, the Board will advise you further in this matter when you shall have submitted the results of your investigations.

The Southbridge Water Supply Company submitted a second application, Oct. 14, 1893, stating that they had made the investigations of the larger sources of supply suggested by the Board, to which the Board replied as follows : —

Boston, Dec. 8, 1893.

The State Board of Health received from you on Oct. 16, 1893, a second application with regard to increasing the water supply of the town of Southbridge, and at a subsequent date received a plan of a storage reservoir which it is proposed to build on Hatchet Brook.

The Board has caused an examination of the premises by one of its engineers, and analyses of the water from Hatchet Brook at the site of the proposed dam, from one of its principal tributaries and from Hatchet Pond to be made. The examination and analyses showed the water to be free from pollution, and that it is soft and of suitable quality for all the purposes of a public water supply. In order to maintain the purity of the water when it is stored, the reservoir should be prepared for use by the removal of all soil and vegetable matter from its bottom and sides.

With regard to the quantity of water, this source with a storage reservoir constructed in accordance with the plan submitted should furnish in the driest year a sufficient quantity of water for a population considerably in excess of the present population of Southbridge, and it is capable of still further development.

The Board therefore concludes that Hatchet Brook at the proposed point of taking is a suitable source of water supply for the town of Southbridge.

**SOUTH DEERFIELD.** The South Deerfield Water Company applied to the Board, Nov. 17, 1893, for its advice as to the propriety of taking Clapp's Trout Brook as a water supply for South Deerfield. The Board replied as follows : —

BOSTON, Dec. 14, 1893.

Clapp's Trout Brook is a small stream which flows down the easterly slope of the range of hills situated about two miles west of the village of South Deerfield. North and south from this brook there are two much larger streams which flow from the same range of hills, namely, Roaring Brook, in the town of Whately, and Mill River, of which Clapp's Trout Brook is a branch, in the town of Conway. Examinations of all of these sources, by an engineer of the Board, and analyses of the water have been made. The analyses show in all cases a water of excellent quality, slightly harder than most of the drinking waters of the State, but yet not hard enough to be objectionable on this account. There was little difference in the hardness of the samples from Clapp's Trout Brook and Roaring Brook, though the latter had a slight advantage in this respect. The sample of water from Mill River was considerably harder than either of the others.

The quantity of water which Clapp's Trout Brook will furnish in a very dry year cannot be accurately estimated from the information now in the possession of the Board. It is obvious, however, from an examination of the territory and of the State map, that the area drained by the brook is quite small, and it is doubtful if this source will furnish enough water in a dry year to supply the village of South Deerfield, after the water has been generally introduced.

Roaring Brook will certainly furnish all the water required, and Mill River, above the point where its water can be diverted to the village by gravity, will probably furnish a sufficient quantity of water. The latter source has the objection, however, that it is much further from the village.

With its present information the Board does not advise the adoption of Clapp's Trout Brook as a source of supply for the village; but it might modify its views if surveys should show that the watershed has a larger area than is now supposed, or should show that it is feasible to build a reservoir or reservoirs upon it, in which to store a sufficient amount of water to tide over dry periods. There seems to be no doubt that a satisfactory supply of water can be obtained from Roaring Brook.

The Board advises you to have further investigations made to determine whether Clapp's Trout Brook will furnish a sufficient supply of water, and, if it will not, to determine whether it is not feasible to obtain a supply from Roaring Brook. When you have further information to present the Board will advise you further in this matter.

STOUGHTON. The water commissioners of Stoughton sent a communication to the Board, Sept. 7, 1893, stating that works recently completed for supplying water to the town had proved wholly inadequate, and that the commissioners desired the advice of the Board relative to taking some new source or devising some method of obtaining a larger supply from the present plant. The Board replied as follows : —

Boston, Oct. 13, 1893.

In April of last year the Board received from you an application for its advice with regard to a new water supply for the town of Stoughton, in which you designated the region near Knowles Brook and Muddy Pond for the consideration of the Board. In the reply to this application, dated May 5, 1892, the Board, in giving the relative capacities of the two sources mentioned, estimated that the Muddy Pond source would furnish a supply for nearly if not quite double the present population of Stoughton, but qualified the statement by saying that “these estimates are based upon the assumption that loose gravelly ground can be found in both of these locations to a depth of from thirty to forty feet, and may require modification if examinations of the ground, which should be made before any final decision is reached, show that this is not the case.” The reply concluded with the following statement : — “The Board is therefore of the opinion that the most appropriate source from which to obtain a water supply for Stoughton is the ground in the vicinity of Muddy Pond, provided further examinations show that porous material at this place is of sufficient depth and extent.”

The new well has been located one-quarter of a mile or more below Muddy Pond, and, owing to its location, the slight depth to which the water in it can be drawn down with the present arrangements for taking water, and probably, also, to the somewhat impervious nature of the material in which the well was sunk, the quantity of water which it will supply is small. Under the present conditions it is obviously desirable to bring additional water to the works already constructed, if it can be done at a reasonable cost, rather than to make any radical changes in the works.

Near the upper end of Muddy Pond, as you well know, there are many large springs outcropping at the base of the high land which partially surrounds the pond. There is no reason to doubt that this spring water, as it comes from the ground, is of excellent quality ; and if a sufficient quantity of such water can be turned into the present pump well it would furnish a most excellent water supply for the town.

The outflow from Muddy Pond represents quite correctly the total volume of water furnished by the springs above referred to, and by such other springs as may be located in the bottom of the pond or in the swamp surrounding it. A measurement of the outflow from the pond made on April 26, 1892, showed the volume to be 1,410,000 gallons per twenty-four hours, and another measurement made on Sept. 11, 1893, showed that the flow was then fully 1,000,000 gallons per twenty-four hours. The comparatively small difference between the measurement made in the spring of the year, when the flow would naturally be greatest, and in the autumn, when the flow would naturally be low, shows that the yield of these springs is remarkably constant.

The smaller quantity of water is about four times as large as the average daily quantity required to supply the present population of Stoughton. It would not be fair, however, to reckon that this source would supply four times the present population of Stoughton, because, during dryer seasons, the springs are likely to be lower than at the present time; and provision is also to be made for the maximum rate of consumption in summer, rather than the average rate throughout the year. There now appears to be an abundant supply of spring water for a much larger population than that of Stoughton entering the pond from the springs, which can be conveyed by an intercepting pipe to the present works. The Board would therefore advise that provision should be made for intercepting the spring water which now finds its way into the pond before the water has been exposed to the light or come in contact with the vegetable matter in the swamp surrounding the pond, and for conveying the intercepted water to the present works.

While the main feature of works for carrying out the advice above given is a pipe tapping the springs and extending from them to the present works, there are many precautions which should be taken to insure success. The attempt should be made to collect *all* of the spring water which enters the pond, and for this reason the intercepting pipe should be everywhere at a lower level than the water in the pond. In order to intercept the water of the springs, the pipe through that portion of its length where the springs are located should be laid with open joints and surrounded and covered with a liberal amount of screened gravel. Smaller branch pipes may also be required at those points where the spring water outcrops in the greatest quantity.

The pipe laid from the territory where the water would be collected to the present works should be of large size, say eighteen inches in diameter, so that it will convey the water to the vicinity of

the present collecting well with very little loss of pressure due to friction ; and this pipe should communicate with the 12-inch pipe leading from the collecting well to the pump well. The 12-inch pipe should have a check valve on it above the point where the new pipe connects with it to prevent the water from backing up into the collecting well and being lost by leakage into the ground about this well. It will also be necessary to make the joints of the new pipe water-tight wherever the pressure of the water in this pipe will cause it to leak out through the joints.

In order to concentrate the flow of the whole twenty-four hours so that it can be pumped in the daytime it will be necessary to stop the flow of water from the pipe at night and permit it to back up in the gravel surrounding and in the vicinity of the open-jointed pipe.

The Board would urge upon you the advisability of having this new work done in a liberal and thorough manner so as to insure the collection of all of the spring water without deterioration of quality. The total cost of doing this work thoroughly would be but a very small percentage of the whole cost of the system of water supply for the town, and yet it represents the most important part of the whole work, namely the collection of an ample supply of excellent water.

UXBRIDGE. The committee on additional water supply for the town of Uxbridge applied to the Board, March 18, 1893, for its advice as to the comparative merits of Seagrave Brook and Cold Spring Brook in Uxbridge, and of Mendon Pond in Mendon, as sources of water supply for Uxbridge. The Board replied as follows :—

Boston, April 4, 1893.

The Seagrave Brook drains so small a territory that, even if extensive storage reservoirs should be constructed upon it, it would not probably furnish a sufficient supply for even the present population of Uxbridge after water was generally introduced in all of the villages ; and this source has no advantage in regard either to the quality of the water or to economy of construction which should lead to its introduction as a temporary source of supply.

Cold Spring Brook, at the proposed point of taking at the old sawmill site, below the Douglas Road, drains so large a territory that its natural flow, supplemented by a comparatively small amount of storage to tide over the dryer portions of the year, would be sufficient to supply Uxbridge with water for many years ; and should the supply at any time prove insufficient, the capacity

of the source may be increased by providing additional storage capacity. A sample of water was collected from the brook near the proposed point of taking on March 25, 1893, which showed the water to be a fairly satisfactory one for water supply purposes. The sample was collected, however, at a time when the streams were swollen by the water from melting snow, and the analysis may, therefore, differ considerably from the analysis of the water at other seasons of the year.

The principal objection to this source is its low level, which makes it necessary to pump the water and consequently increases both the first cost of the works and the annual cost of maintenance. When compared with Mendon Pond it seems probable that the first cost of works from Cold Spring Brook will be as large on account of the cost of a pumping station, offsetting the additional length of pipe required to take water from Mendon Pond; and Cold Spring Brook has the disadvantage of the continued expense of maintaining a pumping station, while the water will flow from Mendon Pond by gravity.

It was not feasible at the time this examination was made to obtain a representative sample of water from Mendon Pond, as the ice was not strong enough to bear the weight of a person, and the water near the edges was affected by the water entering the pond from the melting snow.

To sum up the comparative merits of the different sources, the Board is of opinion that the Seagrave Brook source has no advantage either in regard to quantity, quality or cost. A final opinion in regard to the relative merits of Cold Spring Brook and Mendon Pond in regard to the quality of the water cannot be given at the present time on account of the fact that the few examinations made may not be representative of the quality of the water at all seasons of the year, but it seems probable that Mendon Pond can be made to furnish the better water. The cost of a water supply from Mendon Pond will be very much less than from Cold Spring Brook when the cost of maintaining a pumping station is taken into account.

● **WAKEFIELD.** The Wakefield Water Company requested the advice of the Board, Feb. 23, 1893, relative to introducing "an additional water supply" for Wakefield and Stoneham, from "filtering galleries, wells, or basins upon the banks of that portion of the Saugus River lying within the limits of the town of Wakefield, and above the milldam near the Montrose station of the Salem branch of the Boston & Maine Railroad." The Board replied as follows:—

Boston, April 14, 1893.

From such data as are now available the Board believes that the capacity of the present source (Crystal Lake) in a series of dry years has been practically reached, so that there is need of an additional water supply for these towns. It has already expressed and still holds the opinion that the water of Quannapowitt Lake, one of the sources named in your original act of incorporation, is now unfit for the purposes of a domestic water supply. This opinion as to the quality of Quannapowitt Lake water applies to taking water directly from the lake, but if the water was taken after it had been thoroughly purified by filtering for a long distance through the ground or by any other thorough method of filtration it might be used. It seems probable, however, that the most satisfactory additional supply for the towns of Wakefield and Stoneham can be obtained by taking water from the ground at some point above the dam at Montrose, as indicated in your application.

In the absence of any investigations to determine either the quality or quantity of water which may be obtained from different portions of this territory, it is not feasible to give any specific advice in these respects at the present time.

The city of Lynn, which now takes its supply from sources within the Saugus valley, is in urgent need of an additional supply of water and desires to take it from this valley, and the valley is also nearer other communities in need of additional water supplies than any other large sources not now in use or so much polluted as to be unfit for water supply purposes. While, therefore, the Board believes that the towns of Wakefield and Stoneham should have the first right to a water supply from the portion of the valley within the limits of the town of Wakefield it does not believe that they should control more territory than is necessary for this purpose.

In view of the impracticability of making any fair apportionment of territory at the present time, the Board in its reply to the application of the city of Lynn relative to an additional water supply, concluded that Lynn should be granted the right to take water from any portion of the valley of the Saugus River not already granted by the Legislature to some other town or water company, but that this grant should be subject to the restriction that the towns of Wakefield or Stoneham, or the company supplying them with water, may be authorized to take water from this valley at any point within the limits of the town of Wakefield, and to the extent required to furnish in connection with Crystal Lake, the present source of supply, a supply of water for these towns; provisions to be made in connection with any grant of this character, however, that whenever these towns, or the company supplying

them with water, should take a supply from any source in the Saugus valley other than those already controlled by the Wakefield Water Company they should be required to pay to the city of Lynn a fair proportion of the amount already paid by said city for water or land damages, and if they should utilize to any extent works previously constructed by the city they should pay a fair proportion of the cost of these works.

The Board advises your company to make investigations with reference to obtaining a further supply of water from the ground in the Saugus valley, in the territory referred to in your application, and will advise you further when the results of such investigations are presented. The greatest care should be exercised to prevent the pollution of your present source of supply by the increasing population on its watershed.

**WALPOLE.** The committee on water supply of Walpole applied to the State Board of Health March 9, 1893, for its advice relative to a public water supply for the town, to be taken from the ground in the valleys of Mill Brook and Traphole Brook in East Walpole, tributaries of the Neponset River. The Board replied as follows : —

Boston, April 10, 1893.

In accordance with your request for an early reply to your application relative to a water supply for the town of Walpole, the State Board of Health has caused a preliminary examination to be made, and finds that the local conditions favor the plan of taking a supply from the ground within the limits of the town, as suggested in your application to the Board. As it is stated in your application that the different sources within the town are to be fully investigated, the Board will make a further reply regarding the merits of these sources after the results of the investigations have been received.

After considering the needs and interests of other towns in the vicinity of Walpole the Board finds no reason to doubt that Walpole should at the present time have the right to any source within its limits. There is one source, however, viz., Traphole Brook, in the easterly part of Walpole, which subsequently flows through the southerly corner of Norwood and then forms the northerly boundary of the town of Sharon, which may in the future be of value to some other community as a source of additional water supply ; and if it should be found that this source is not the best one for Walpole and works should be built to take a supply from another source, the Board is of opinion that any rights which are now

granted Walpole to take a supply from this source should cease. This could be accomplished by including in an act giving Walpole the right to take water from any source within its limits a provision that the right of the town of Walpole to take water from Trap-hole Brook shall become void when the town shall have selected some other source of water supply and introduced water therefrom.

The results of the investigations referred to in the foregoing letter of advice having been submitted, the Board made a further reply as follows : —

BOSTON, June 5, 1893.

The investigations made near the Neponset River, not very far above the Blackburn water privilege and just below Low Brook, showed very satisfactory results as regards the porosity of the material, the freedom with which water could be pumped from the test wells and the quality of the water. Taking these results in connection with an examination of the surrounding territory and the size of the streams, the Board finds no reason to doubt that an ample supply of excellent water can be obtained from a well or wells located in the porous material in this vicinity.

WALTHAM. The water commissioners of Waltham applied to the State Board of Health July 31, 1893, asking for a re-examination of their sources of water supply, and for the advice of the Board as to the measures requisite to improve the quality of the water supplied to the city, and to prevent the recurrence of the offensive tastes and odors which were liable to affect it. The Board replied as follows : —

BOSTON, Dec. 22, 1893.

An examination of your collecting well and distributing reservoir was made promptly by one of the engineers of the Board, and samples of water were taken for analysis, which showed that the conditions were on the whole substantially the same as they were on Oct. 3, 1892, when the Board replied to a similar application made by you, and advised protecting the water from the light both at the well and at the distributing reservoir. The results of these analyses were sent you; and, as you then decided to proceed at once with the covering of the well, it was thought best to defer making the formal reply until it was feasible to include in it the results of further investigations, to ascertain the character of the water entering the well at different points and the effect of covering the well.

An examination was made to ascertain the temperature of the water entering the well at the bottom, at different points around its circumference, and it was found from thirteen observations, made on Sept. 9, 1893, that the average temperature of the water entering the well was 55.7 degrees, while at the same time the temperature of the river water was 68 degrees. These results indicated that no large proportion of the water filtered from the river by any very direct course, but there was a slight difference (3.4 degrees) in the temperature of the water at different points, which indicated that there might be a difference in the source and quality of the water entering different parts of the well. An attempt was therefore made to obtain samples of water entering the well at different points at the bottom, before it had mingled with the water already in the well, but it was not found feasible to do this.

Since the well has been covered two samples of water have been received from it, one collected November 14, and the other Dec. 12, 1893. These samples are entirely free from the microscopical organisms which were always found in the well before it was covered, and are clear, colorless and free from odor.

It is now feasible for the first time to ascertain the true chemical character of the water which enters the well, because, before it was covered, its character changed so rapidly, owing to the vegetable growths in the water, as to materially affect the results. There is nothing in the present analysis of the water to indicate that it is at the present time other than an excellent water for the purposes of a public water supply. The free ammonia, however, is somewhat higher than it would be in a water which had received the highest degree of purification by filtering through the ground, and it will be of interest to observe subsequent analyses of the water to see whether this constituent increases or diminishes.

With regard to the samples from the distributing reservoir it may be said that they show that the water in the reservoir is in substantially the same condition as in the past, and that it contains an abundant growth of the minute vegetable forms which give the water an unpleasant taste and odor.

The Board would therefore repeat its advice of last year, that by covering your present reservoir or building a new covered reservoir, as may be found best, you provide for conveying the water from the source to the water consumers without permitting it to be exposed to the light at any place.

WEBSTER. The water commissioners of Webster applied to the Board, June 23, 1893, for its advice relative to taking

a supply of water from the ground near Lake Chaubunagungamaug. The Board replied as follows : —

Boston, Oct. 6, 1893.

The State Board of Health has considered your application with regard to a proposed water supply for the town, to be taken from a well located near Lake Chaubunagungamaug, and has caused an analysis of a sample of water from a test well at the site of the proposed well to be made, also an examination of the surrounding territory. The analysis shows that the water is very pure and soft.

The sample probably represented water which was percolating through the ground toward the pond ; while if a large quantity of water should be pumped from the ground at this place, it is probable that a part of it would be derived by filtration from the lake. Judging from the experience at other places in the State, the water obtained in this way from the lake would be so thoroughly changed in its character by filtration that it would not differ to any noticeable extent from the water coming to the well from the land side.

Both the examination of the ground at the site of the well, made under your direction, and a general examination of the surrounding territory, indicate that a large quantity of water can be collected from the ground at this place ; and if the supply should prove insufficient, a supplementary supply of very good surface water can be obtained from the lake. It is desirable, however, that a full supply should be obtained from the ground, on account of the better quality of the water from this source.

WESTBOROUGH. The water commissioners of Westborough applied to the Board for advice, Sept. 26, 1892, relative to the improvement and increase of the public water supply, submitting at the same time a description of a proposed plan. The chief engineer of the Board visited the town, and made such suggestions as seemed necessary for the modification and improvement of the plan, and a new plan was submitted to the Board, Jan. 19, 1893. The Board replied as follows : —

Boston, Feb. 13, 1893.

Your water supply is now derived from two reservoirs, the upper one a storage reservoir of considerable size and the lower one a smaller basin which derives its supply from the upper one by the filtration of the water through the intervening porous ground. You find that the quality of this filtered water is very much better

than that of the water in the upper reservoir, but that at times the quantity is not sufficient to supply all of the water needed, and you therefore have to draw some of the water directly from the upper reservoir; moreover, the upper reservoir sometimes overflows into the lower one, injuriously affecting the quality of the water in it.

What is now desired, therefore, is a means of increasing the supply of filtered water during portions of the year and a means of diverting the overflow of the upper reservoir from the lower one.

The plan now submitted shows a contemplated channel for diverting the waste water from the upper reservoir past the lower one, and with the accompanying communication explains the result of certain tests which have been made with reference to the present conditions under which water is now filtering from one reservoir to the other, and of other tests made to determine the means by which the filtration may be facilitated.

Judging from the experiments which you have made, it seems quite certain that a material increase in the amount of filtered water can be obtained at a moderate expense by digging a ditch with sloping sides down into the sand and gravel at the shore of the upper reservoir between the dam and the waste way, this ditch to be separated from the water in the reservoir by an embankment extending above high water mark. This ditch should also be divided into sections, each of which should communicate with the reservoir by means of a pipe provided with a gate by which the water can be shut off during those portions of the year when enough water naturally filters through the ground, or when it becomes necessary to clean any section of the ditch so as to expose a fresh sand surface. The pipe and bottom of the ditch should either be placed at the lowest practicable level in the beginning, so that the system will operate when the upper reservoir is drawn down several feet, or they may be placed at a higher level in the beginning and subsequently lowered when the water recedes.

The experiments show that a ditch of this kind would let the water into the ground much more freely than it now gets in through the nearly impervious material at the bottom of the reservoir.

On the opposite or north side of the waste way a similar construction could be used to facilitate the filtration of water, but the ditch should be placed far enough back from the edge of the reservoir so that it will be wholly in clean sand or gravel below the surface of the water in the reservoir.

The contemplated filtering drain, intended to collect water from the ground and discharge it into the lower basin, if placed with its bottom nearly at the level of low water in the lower basin, would

undoubtedly increase to a considerable extent the quantity of filtered water. To avoid the danger of imperfect filtration, however, it would be desirable to limit its length to 150 feet from the shore of the lower basin rather than to make it 235 feet long, as shown upon the plan. This drain should connect with the lower basin by a pipe provided with a gate so that it can be shut off during those portions of the year when enough water naturally filters through the ground, and thus avoid an unnecessary draft upon the upper reservoir.

The new channel to divert the overflow from the upper reservoir past the lower basin is a very desirable feature, and if by removing the soil and fine material this channel can be prepared so that all the material beneath it will be sand or gravel it may also be feasible to use it as a supplementary filtration area in cases of emergency. In order to do this it would be necessary to lay a pipe to bring water from the upper reservoir to the channel, and to erect temporarily a low dam near its lower end.

WEST SPRINGFIELD. The water commissioners of West Springfield applied to the State Board of Health May 1, 1893, for its advice relative to taking an additional water supply from certain specified sources in that town and in Agawam. The Board replied as follows: —

BOSTON, June 1, 1893.

The State Board of Health has considered your application with regard to a proposed additional water supply for your town, including the village of Mittineague, which is at too high a level to be supplied from the present source. You have called the attention of the Board to the Craig Spring and Silver Stream, which can be utilized to supply the village of Mittineague by pumping, to the Leonard Brook in Agawam, which can be used to supply a portion of the lower village by gravity, to the Lathrop Spring and Hyde Brook, which can be diverted into the present reservoir, and to a more distant source, viz., a spring and brook at the Bear Hole, so-called, in the north-westerly part of the town, from which water would have to be supplied by pumping.

All of these sources have been visited by the engineer of the Board, and from all except Silver Stream samples of water have been collected and analyzed, and copies of the analyses are transmitted herewith, together with the average analysis of water from the present storage reservoir for the year ending in May, 1888.

The Craig Spring will furnish a soft water, and one of very good quality, provided it is collected by means of pipes leading to a

well, or by other suitable works, without exposure to the light, and when pumped is stored in a reservoir which is also covered to exclude the light. Care would also have to be taken to prevent any contamination by surface water running down the ravine in which the spring is situated.

The water of the Leonard Brook is soft and of very good quality.

The sample of water from the Lathrop Spring was necessarily collected after the water had passed through a rank growth of vegetable matter, which may have affected the analysis to some extent. This water is harder than the other waters examined. There seems no reason to doubt, however, that if taken directly from the ground and diverted into the present reservoir it would not change the character of the water in the reservoir enough to be objectionable.

The sample from Hyde Brook had a moderate color, indicating that this water is affected to some extent by contact with vegetable matter in swampy places. At the time the sample was collected, the water, though not as desirable as the spring waters, would be classed as a fairly good water for all purposes, but it is not feasible to tell from a single examination in the spring of the year what the character of this water would be in summer.

The water of the spring at the Bear Hole is of excellent quality, though its hardness is about twice that of the present water supply. The degree of hardness, however, is not great enough to make the water objectionable for water supply purposes. Bear Hole Brook, at the time the sample was collected, was receiving the overflow from Ashley Pond, and the quantity of water was unusually large. Under these circumstances the analysis would have but little value as an indication of the average quality of the water. The water had less color than Hyde Brook, but contained rather more organic matter. The degree of hardness was nearly the same as that of the water from the spring near it.

The plan proposed by you, of establishing a pumping station at the Craig Spring and supplementing the present supply to the lower village by introducing water from Leonard Brook, and connecting the Lathrop Spring with the present reservoir, has the merit that it will add to the present supply a considerable quantity of very good water by a comparatively small expenditure, and it may be wise to carry out this plan. The Board does not, however, have sufficient information as to the capacity of the present source in very dry years, or as to the amount which the supplementary sources will furnish in such years, or can be made to furnish by the construction of additional storage reservoirs, to enable it to advise definitely as to whether it is better to carry out this plan to

make the Craig Spring and the present reservoir the main source of supply, to be supplemented by such other sources in the vicinity as will supply the lower village by gravity, or whether it is better to go at once to a greater distance to obtain a supplementary supply from a source which will furnish a larger quantity of water. In order to obtain such information it would be necessary for you to employ an engineer skilled in the design and construction of water works to make a more complete study of this question, and the Board advises that this be done.

WHITMAN. The committee on water supply of the town of Whitman applied to the Board, April 12, 1893, for its advice relative to a public water supply from certain specified sources in that town and the towns of Hanson and Pembroke. The Board replied as follows:—

Boston, May 4, 1893.

In this application you make special mention of Maquam, Oldham and Big Sandy Bottom Ponds and Silver Lake. The Board has caused examinations to be made of these and other ponds in the vicinity. Complete chemical and microscopical examinations have been made of samples of water from Maquam, Oldham, Furnace and Big Sandy Bottom Ponds and Silver Lake, and less complete examinations of samples from Indian Head Pond and Factory Pond in the town of Hanson and Stetson's Pond in the town of Pembroke. Copies of these analyses are transmitted herewith.

The water of Indian Head and Factory ponds has a very dark color, and in other respects these ponds are less desirable than some of the others, so that they may be discarded from the list of desirable sources. Stetson's Pond presents no advantages either as to the quality or quantity of water as compared with Oldham Pond, and on account of its greater distance is a less available source for Whitman.

The water of Maquam Pond is practically colorless and in most other respects is a very satisfactory pond water. It had, however, at the time of the examination slightly more odor after standing in a bottle, and contained a greater number of microscopical organisms than any other sample of which a complete examination was made. All surface waters contain a greater or less number of these minute organisms, which are the cause of the odors noticed, and both the numbers and the amount of odor are liable to vary from time to time, so that too much significance should not be attached to the comparisons of only a single series of analyses. It is not feasible to tell from the information at present available whether or not Maquam Pond will furnish sufficient water to meet the requirements of the town of Whitman even in the near future, and this

source should not, therefore, be adopted in any case without making provision for supplementing the supply from some other source when necessary. In order to form an opinion as to whether this pond will furnish enough water to warrant taking a supply from it in the beginning, it would be necessary for you to ascertain by surveys the size of the watershed from which its supply is derived, and to make investigations to determine how much, if any, water is liable to be lost by filtration through the ground into other ponds.

Oldham Pond will furnish an abundant supply for the town for a very long time in the future, and the analysis indicates that the water is of fairly good quality at the present time. It has only a moderate amount of color and contains about the usual amount of organic matter, and in its present condition would be a satisfactory water for all purposes of a public water supply, though not as good as either the water of Maquam Pond or Silver Lake.

The analysis of a sample of water from Furnace Pond differs but little from that of a sample collected from Oldham Pond, but Furnace Pond has no advantages which should lead to its selection as a source of water supply for Whitman.

The water of Silver Lake is practically colorless and in other respects it is a better water than any other of the waters analyzed. This would undoubtedly be a satisfactory source both with regard to quantity and quality.

Big Sandy Bottom Pond has been used for years by the towns of Abington and Rockland and has proved to be an excellent water. The quantity which this source will furnish is more than the amount of water consumed by the three towns of Abington, Rockland and Whitman at the present time, so that for a time this source might be sufficient for all of the towns, but at a later period it would be necessary either to supplement the supply from some other source or for one of the towns to introduce an independent supply.

The information now in possession of the Board with regard to the proposed sources of water supply is too limited to enable it to advise as to the most appropriate source for the town, and it makes this preliminary reply at the present time because it understands that it is desired for use at a town meeting to be held soon. The Board would advise that a survey be made, as before suggested, to determine the size of the watershed of Maquam Pond, and that analyses should be made monthly of the waters of Maquam and Oldham ponds and of Silver Lake to determine the relative quality of these waters throughout the summer. The State Board of Health will co-operate with you by causing these analyses to be made if you will collect the samples of water, and will advise you further with regard to the proposed sources if you so request.

## SEWERAGE AND SEWAGE DISPOSAL.

The following is the substance of the action of the Board in reply to applications for advice relative to sewerage and sewage disposal : —

ANDOVER. The sewer commissioners of Andover, having been authorized by the town to report a plan of sewerage to the town, applied to the State Board of Health, June 8, 1893, stating that before reporting a general plan to the town they desired to know whether such a plan, involving the discharge of crude sewage into the Shawsheen River, would be approved by the State Board of Health. The Board replied as follows : —

Boston, July 7, 1893.

The Board is of opinion that, while it is not permissible to discharge the sewage of any large portion of the town into this river, it may be permissible for the present to discharge the sewage from the low land bordering the river into the river below the dam at Frye Village. In making a sewerage plan, therefore, provision should be made for carrying as much of the sewage of the town as can be conveyed by gravity, either to suitable porous land, where it can be purified by filtration before being discharged into the Shawsheen River, or to the Merrimack River.

ATTLEBOROUGH. The committee on drainage of the town of Attleborough applied to the State Board of Health, Jan. 16, 1893, for its advice relative to “the drainage of that portion of the village and town located on the watershed of Thacher Brook.” The Board replied as follows : —

Boston, Feb. 6, 1893.

The plan submitted shows the general character of the proposed improvement, which provides for lowering the channel of Thacher Brook, either in its present or a new location, and the substitution, for a portion of the way, of a covered drain for the open channel.

It is understood from the statements made by your committee that it is not proposed to turn any sewage into this channel, but that the sewerage system when constructed will convey the sewage in separate pipes in some other direction. Your committee has also indicated that it is very desirable to lower the level of the ground water in the upper part of the Thacher Brook watershed and near the central portion of the village, in order to avoid damp

or wet cellars, and thereby to improve the sanitary condition of this portion of the town. The high level of the ground water in this part of the village is also shown upon a plan previously submitted to the Board giving the level of the ground water.

The Board finds that the plan now proposed is one to be commended. It is certainly very desirable, for sanitary reasons, that the level of the ground water in the built-up portions of this watershed should be lowered, and it is wise to provide for the improvement of the lower portions of this brook before the design and location of a new channel are hampered and the cost increased by the construction of streets and buildings in the vicinity of the brook.

In addition to the improvement of the main channel the plan also indicates where branch drains emptying into the brook may be built in the streets in its vicinity. It would be desirable before constructing these drains that a complete system of sewerage should be designed for at least this portion of the town, both because the level of the ground water might be lowered by under-drains placed beneath the sewers, thereby rendering separate drainage channels unnecessary, and because the drains might otherwise be placed at such a height as to interfere with the proper grading of the system of sewers. These suggestions with regard to the branch drains may also be applicable to the extreme upper end of the main drain.

**BRAINTREE.** The committee on sewerage of Braintree applied to the State Board of Health June 5, 1893, for advice relative to a proposed system of sewerage for that town, and as to the comparative merits of certain areas proposed for sewage disposal. The Board replied as follows : —

Boston, July 6, 1893.

In this application you outline the general features of a proposed system for collecting the sewage, and suggest, as a method of disposal, pumping it to land where it can be purified. You then ask that the Board will cause the different tracts of land which are available for sewage disposal to be examined at as early a day as possible, and that the Board advise you regarding them.

Three tracts were called to the attention of the Board, one situated on the north-westerly side of Plain Street, just north of the Plymouth branch of the Old Colony Railroad, known as the Plain Street lot, another in the south-westerly part of the town, known as the Mayflower Park lot, and a third in the north-westerly portion of the town, known as the Collins Farm lot.

The Collins Farm lot is unsuitable for this purpose on account of its being located where the effluent from the sewage would find its way both into the present water supply of the city of Quincy and into the territory from which this city was authorized by the Legislature in 1891 to take an additional water supply.

At the Plain Street lot the test pits indicated that the material is of excellent quality for filtering sewage, and the principal objections to it are its proximity to the village of South Braintree and the limited area of suitable land which is available at this place. It is also an objection to this lot, though to a less extent than to the others, that it requires the sewage to be pumped a long distance from the lowest point in the town (where a pumping station would naturally be located), and to quite a high elevation.

At the Mayflower Park lot the test pits indicated that in addition to the coarser sand and gravel there were layers of very fine sand, which, while not preventing the use of the lot for the filtration of sewage, would require it to be applied in smaller quantities per acre, and would therefore require a greater amount of land to dispose of the sewage. The principal objections to the lot are its proximity to several houses, its limited area and the very great distance which the sewage would have to be pumped to reach it.

The amount of land required to purify the sewage of Braintree by intermittent filtration would depend both upon the quality of the land and upon the amount of sewage. In a general way it may be said that from 6 to 10 acres of filter-beds would meet all requirements for a few years, and that it is desirable to have not less than 20 or 30 acres in all to provide for future growth. It does not seem probable that this amount of land can be made available at either the Mayflower Park or the Plain Street location.

As a general result of this preliminary examination the Board is of opinion that, before adopting either of the tracts brought to its attention, it would be advisable for the town to cause examinations to be made to ascertain if a more satisfactory disposal of the sewage cannot be effected by discharging it into the sea at some suitable outlet. The nearness of the village of Weymouth to the lowest point in Braintree suggests that the interests of both communities might be served by united action by the towns of Weymouth and Braintree in the construction of an outlet to the sea; but even if it should be built by Braintree alone it may be cheaper and more satisfactory than the disposal of the sewage upon any of the areas examined up to the present time.

BROCKTON. The sewerage commissioners of Brockton applied to the Board, Sept. 14, 1892, for its advice relative

"3. Will the Board suggest the size of out-of-door filter-beds deemed necessary to make acceptable our second plant?

"4. Can loam be used over the sand in filter-beds?"

The application was accompanied by plans of the proposed plant at the location first indicated, which is an area of low ground bordering on the right or easterly bank of the Shawsheen River, between Main Street, Harding Street and the Boston & Maine Railroad; and subsequently a report was submitted relating to the proposed method of operation of the plant, and a sample of the sand intended to be used.

The essential features of the plan are settling tanks for the removal of the suspended matters from the sewage by sedimentation; filter-beds having an area of 2,800 square feet, and containing about 5 feet in depth of filtering material, through which it is expected to filter sewage from the settling tanks intermittently at a rate of 3,200,000 gallons per acre daily; and a secondary filter-bed, having an area of 2.3 acres, to be used for the filtration of the effluent from the first-mentioned filters by application to sand beneath a layer of loam. By the alternative plan, the last-mentioned filter-bed may be omitted, but the effluent in either case would be discharged into the Shawsheen River.

The Board has carefully considered the proposed scheme, and finds that it is a thoroughly impracticable one for the disposal of the sewage of the town of Andover.

The settling tanks into which the sewage would be discharged as it came from the main sewer cannot be expected to remove more than a very small portion of the suspended matter. Experiments at Lawrence with reference to the removal of organic matter from sewage by sedimentation have shown that by allowing sewage to settle for four hours about 18 per cent. of the organic matter, as indicated by the albuminoid ammonia, was removed. The consumption of water in Andover for the year 1894 averaged 328,000 gallons per day, and it is not unreasonable to expect that the amount of sewage to be disposed of after the sewerage system has come into general use may be in the vicinity of 200,000 gallons per day. With this quantity of sewage flowing, the time occupied by it in passing through the proposed settling tanks would not average more than two hours, or about one-half the time allowed in the experiments at Lawrence, and during the portion of the day when the flow was greatest the sewage would pass through the tanks in less time; moreover, there would be a constant flow of sewage through the proposed tanks, while in the case of the experiments at Lawrence the liquid was not disturbed.

The in-door filter-beds for the rapid filtration of the sewage after it has passed through the settling tanks are altogether inadequate for the purpose, and would very quickly become clogged, so that the required quantity of sewage could not be made to pass through them.

ing the works, the Board is of opinion that a pumping station should not be a source of offence to the neighborhood.

The provision of an overflow from the receiving reservoir and of blow-offs from depressions in the force main, where it crosses under the Salisbury Plain and Coweaset rivers, is a wise precaution; but these should be considered only as a provision for unforeseen emergencies and should never be used in the ordinary operation of the works.

The ground where the filter-beds are to be located has been very thoroughly examined by means of test pits. The material is of excellent quality for the filtration of sewage and the water level in the ground is at a considerable distance below its surface. These natural features, together with the careful manner in which it is proposed to construct the beds and their appurtenances, will permit them to be used for the disposal of an unusually large amount of sewage.

It has also been found, since the water supplied to the city has been pumped, and therefore measured, that the amount of water consumed per inhabitant is unusually small; and the amount of sewage will also be unusually small, in proportion to the population, if the ground water is kept out of the sewers, as is now proposed.

All of these facts lead the Board to conclude that the area to be used for filtration, although smaller than it is customary to recommend, will be sufficient for at least the first few years of the operation of the works, after which it will be necessary to extend the area.

The land in Brockton, lying easterly of the proposed filter-beds, which slopes from Pearl Street to the cranberry meadow, might be used to a limited extent for filtering sewage, but the test pits show that layers of an impervious clayey material are found in many places at from  $3\frac{1}{2}$  to  $6\frac{1}{2}$  feet below the surface and that the water stands in the ground much nearer the surface than on the other side of the street. This land could only be used to dispose of a comparatively small amount of sewage. The land in Brockton north of and across Daley Brook from the proposed filter-beds is better than that on the easterly side of Pearl Street but not as good as that where the filter-beds are located. This land would be fairly well adapted for the filtration of sewage.

The best land in this vicinity for the extension of the filter-beds lies just west of them, within the limits of the town of Easton. This land is similar in character to that where the filter-beds now proposed are located and is superior in quality, topography, character of material and distance from habitations to the land either east or north of them.

Since the proposed plan involved the taking of certain land within the limits of the city, further action of the Board was required under the provisions of chapter 124 of the Acts of 1890. A public hearing was therefore held by the Board, after which the following reply was sent to the mayor of Brockton : —

Boston, April 17, 1893.

The State Board of Health has received your petition dated March 25, 1893, made in behalf of the city of Brockton under the authority of chapter 124 of the Acts of 1890, entitled "An Act providing for the purchase or taking of land by cities and towns for the purification and disposal of sewage," asking the Board to approve the purchase or taking by said city of certain lands in Brockton for the purification and disposal of its sewage. Said lands are described in said petition and shown on an accompanying plan, as follows: "24 acres and 128.9 rods, being lands of Charles C. Manley; 20 acres and 58.7 rods, being lands of heirs of Salmon Copeland; 1 acre, being lands of David Frost; 2 acres and 73.28 rods, being lands of Milo Manley; 121.77 rods, being lands of Augustus Remick; 2 acres and 70.25 rods, being lands of George Howard."

In response to this petition the Board gave a public hearing at its office in Boston, on April 10, 1893, after due notice of said hearing by publication in the Brockton "Enterprise" and Brockton "Dispatch." Having thus complied with the requirements of the law the Board after due consideration herewith approves the purchase or taking of the premises described in said petition and shown upon the plan which accompanied it.

FRAMINGHAM. The selectmen of Framingham applied to the Board for advice relative to a proposed plan for the disposal of the water of the underdrain of the sewerage system of South Framingham, by pumping and final discharge into Bannister Brook. The Board replied as follows : —

Boston, Feb. 6, 1893.

Your application to the State Board of Health dated Jan. 23, 1893, for advice with regard to the disposal of the water, which is now discharged from the underdrain beneath the Framingham sewers into the water supply of Boston, by pumping this water into Bannister Brook at a point north of Hartford Street, beyond the watershed from which said supply is derived, has been carefully considered

The opinion of the Board with regard to the desirability of diverting this water from the water supply of Boston has already been given in its reply to the Board of Selectmen of Framingham dated Sept. 2, 1890.

With regard to the method of disposal now proposed, the principal features from a sanitary stand-point are the open reservoir near the pumping station, in which is to be stored the water from the underdrain during the night or at such other times as the pumps are not in operation, and the location of the final point of discharge. While it is not probable that the open reservoir will prove objectionable in any way yet the Board considers it advisable that it should be made as small as is consistent with a fair degree of economy in pumping. The capacity stated in the report which accompanied the application seems unnecessarily large.

With regard to the final disposal of the water from the underdrain by discharging it into the upper end of Bannister Brook north of Hartford Street, and beyond the watershed from which the city of Boston derives its supply, the Board is of opinion that this method of disposal is permissible for the present; but if the character of the water should deteriorate it may become necessary to discharge it upon a small filtering area, and it would be well to have the outlet where two or three acres of suitable filtering material may be secured.

**HOLYOKE.** The mayor of Holyoke applied to the State Board of Health, Feb. 13, 1893, for advice relative to a system of sewerage and sewage disposal for the villages of Elmwood, Oakdale and Springdale, having an outlet into the Connecticut River, opposite the trotting park in the lower part of the city. The Board replied as follows:—

Boston, March 2, 1893.

The Board is of the opinion that the sewage of these sections of your city may for the present be discharged into the river at the place indicated, but advises that the lower portion of the sewer should be so designed and constructed that the dry weather flow will be carried well out into the river by means of a pipe of moderate size leading from the bottom of the sewer, thereby preventing the fouling of the shore.

**LEICESTER.** The water commissioners of the water supply district of Leicester applied to the Board, Jan. 23, 1893, for advice as to a plan of sewerage and sewage disposal for

the village of Leicester. At a later date, March 1, they submitted a legislative document (House Document 385), stating that the committee on drainage requested that the bill accompanying the petition of the commissioners should be accompanied with the advice of the State Board of Health. The Board replied to this application as follows :—

Boston, March 3, 1893.

In reply to your request of March 1, relative to the application dated Jan. 23, 1893, of the Leicester Water Supply District, for advice in the matter of the disposal of the sewage of said district, the Board would state that it will be impracticable to advise until the snow disappears, so that a proper examination of the ground can be made.

With regard to the other matter mentioned, namely, the bill (House Document No. 385) extending the authority of the water commissioners of the district so that they shall also be a board of commissioners of main drains, common sewers, sidewalks and cross-walks, and providing that the district may raise money for carrying out the provisions of the act, the principal object appears to be to confer powers upon the district and its water commissioners with regard to the construction of main drains, common sewers, sidewalks and cross-walks, similar to those already possessed by towns and their selectmen. So far as the bill provides for the transfer of power from the town and its selectmen to the district and its water commissioners, the Board does not consider it within its province to advise.

In looking at the provisions of the bill in other respects, it is noticed that while it provides for the construction of main drains and common sewers, and for taking the land which may be necessary therefor, it does not authorize the construction of sewage disposal works or the taking of land for this purpose should the purification of the sewage be found necessary. The Board would therefore suggest that the bill might with advantage be modified so as to give the required authority in these respects, and herewith transmits a copy of the bill with suggested modifications to accomplish this result.

Should the Committee on Drainage think it advisable to limit the power granted to the water supply district with a view to preventing any improper disposal of the sewage, it might require the system of sewerage adopted and the land taken for sewage disposal, should any be required, to be subject to the approval of the State Board of Health. This might be accomplished by adding after the word "therefore" in section 5, line 8 : —

Provided, however, that any system or systems of sewerage, drainage or sewage disposal constructed under the provisions of this act shall be in general accordance with some plan or plans approved by the State Board of Health, and no land shall be taken for sewage disposal purposes without the approval of said Board.

The Committee on Drainage may also desire to restrict the territory within which land can be taken, by adding after the word "land," in section 5, line 7, the words "within the limits of the town of Leicester."

The final reply of the Board relative to this plan of sewage disposal was as follows : —

Boston, June 1, 1893.

The situation of the village upon the hill is such that nearly all of the sewage can be carried by a single system to the westerly side of the town in the vicinity of Rawson Brook, so called, or it is feasible to provide two systems, one of which would convey the sewage of rather more than half of the village to the above indicated location on the westerly side of the town, while the other would take the sewage from the remainder of the village in an easterly direction. An examination of the whole territory indicated that it would be well to take as much sewage as possible in a westerly direction to a point near the Rawson Brook.

After considering all of the conditions affecting the discharge of the sewage into Rawson Brook, the Board has reached the conclusion that such discharge should not be permitted even in the beginning until the sewage had been at least partially purified by the removal of the greater portion of the suspended matter. In the future a more complete purification of the sewage may be found necessary.

The best method of purification cannot be determined without a more extended examination of the ground than it is feasible for this Board to have made, and your town is therefore advised to employ a competent engineer to make the necessary surveys and devise a system for the purification of the sewage to at least the extent above indicated. The Board will advise further with regard to such system when the plans are submitted by you.

Where sewage is to be purified the smaller the amount of water to be taken care of, the less the difficulty of purification. The Board therefore commends your plan for adopting a system of sewers from which all storm water is to be excluded, and would further advise the exclusion of as much ground water as it is feasible to exclude.

The town of Leicester, having obtained an act from the Legislature requiring the approval of its plans by the State Board of Health (chap. 181, Acts of 1893), submitted plans to the Board, June 30, 1893, a statement of which, together with the approval of the Board, are as follows : —

Boston, Dec. 30, 1893.

Under the provisions of chapter 181 of the Acts of 1893, entitled "An Act to authorize the Leicester Water Supply District to construct and maintain a system of sewerage and drainage," the State Board of Health received from you on June 30, 1893, a written statement of your plan for the sewerage of the village of Leicester. This statement of your plan, as subsequently amended and submitted in a new draft dated Dec. 22, 1893, is as follows : —

13 BEACON STREET, BOSTON, MASS.

*To the State Board of Health.*

The water commissioners of the Leicester Water Supply District having received your reply of June 1, 1893, to their application for advice in relation to the disposal of the sewage of the village of Leicester, submit, for your approval, the following plans for its disposal.

In accordance with your suggestion, we propose to carry the sewage as far as possible to the westerly side of the village, and remove all the organic matter in suspension, so far as practicable, before discharging the effluent into Rawson Brook.

To accomplish this end, the separate water carriage system is to be adopted, to the extent of excluding all street or storm water, roof water and ground water, so far as feasible, the sewers to be flushed only when necessary with clean water from the mains.

The suspended matter is to be removed, as far as practicable, by allowing the heavier portion to settle in the tank (to be hereafter described), and by mechanical straining, if necessary, of the lighter part.

In order that the effluent may contain the smallest possible quantity of organic matter in solution, the separation is to be effected while the sewage is fresh.

The natural conditions of the location of the village on the slope of a hill are to be utilized as far as practicable by laying the sewers in accordance with approved forms of sewerage construction, to line and grade, with manholes at material changes of line and grade, at points of intersecting sewers, and wherever necessary, so as to insure easy cleaning out, and the most rapid flow and concentration of the sewage to the point of disposal.

For this purpose, 8-inch, 9-inch and 10-inch Akron salt-glazed pipe is to be used. Ground water is to be excluded by using cast-iron pipe when crossing wet, swampy land not easily drained outside of the highway, and by carefully making the joints and plugging the branches for particular sewers.

All the sewage for the present is to be collected at a point on Pine Street, 1,100 feet south of Main Street, and thence carried in a 10-inch pipe, laid at a grade of about 0.4 per cent., in a south-westerly direction, as shown by an accompanying plan, a distance of about 1,250 feet, to the top of a small knoll, and there discharged into a settling tank.

This tank is to be built either of brick or field stone, laid in cement mortar and plastered on the inside. It is to be covered with a roof or building. It is to contain not less than 600 cubic feet of sewage.

The overflow pipe from the tank is to be on the opposite side from where the sewage enters, and provision is to be made for breaking the force of the stream which enters the tank, so as to make the sewage flow quietly through it, and for preventing the floating scum from passing out through the overflow pipe.

The sewage passing from the tank is to be further purified as far as practicable by flowing it over land, or through a series of ditches, to Rawson Brook; but provision will be made so that the sewage will not have to run continuously in any one channel.

At the bottom of the tank an 8-inch gate connection with an 8-inch pipe is to be laid at a down grade of about one foot to the hundred to the point of discharge. Through this pipe the sewage or sludge which settles at the bottom of the tank is to be discharged once or twice a week, as may be necessary, upon ground thoroughly underdrained and levelled, so as to have a slight downward pitch from the point of discharge. This ground is to be ridged around the outer edge, so that the sludge may be distributed somewhat evenly over the surface. After the water which it contains has percolated through the drained surface, the solid refuse is to be carted away. Two or three beds of this kind will be prepared to be used alternately, and provision will be made for discharging the sludge brought by the 8-inch pipe upon them.

By extending the 8-inch pipe further in a southerly direction, other sludge beds can be prepared when necessary to meet future requirements.

It is proposed to acquire the knoll or ridge upon which the tank is to be located, and other knolls or ridges southwesterly therefrom, and all of the land between these knolls or ridges and Rawson

Brook, for the disposal of the sewage, and to purify the sewage upon this land as far as it may be found practicable to do so.

(Signed)

H. O. SMITH,  
C. W. WARREN,  
D. BEMIS,

*Water Commissioners.*

LEICESTER, Dec. 22, 1893.

The Board has caused a careful examination of the foregoing plan submitted by you to be made, and hereby approves said plan.

**NORTH BROOKFIELD.** The selectmen of North Brookfield applied to the State Board of Health, July 23, 1893, for advice relative to an extension of their existing system of sewerage and to an improved method of sewage disposal. The Board replied as follows:—

Boston, Sept. 8, 1893.

The plan, as set forth by the application and plans submitted, provides for the extension of the present main sewer to the northerly end of the town farm, the lower portion of said sewer to be an inverted siphon of iron pipe. At the outlet of the siphon a settling tank is shown, and provision is made for cleaning it by discharging its contents through an 8-inch pipe extending from the bottom of the tank down the hill to a sludge bed. The plan also shows another pipe extending down the hill, to serve as a main carrier of a system for distributing the settled sewage. The other carriers are not shown, but it is understood that they are to consist of ditches dug along the hillside, and having only a slight slope from the main carrier to their lower ends. It is further stated that the sewage can be turned upon about 17 acres of mowing and tillage land of a sandy nature, and thus dispose of the same by broad irrigation, and that there is other land upon the town farm which could be easily used in the future if necessary. The quantity of sewage at present is said to be about 50,000 gallons per day.

Under the conditions which exist in the present case it is advisable to screen the sewage, rather than to settle it, and thus avoid the possibility of producing offensive odors when the contents of the settling tank are discharged upon the sludge bed. The inverted siphon can undoubtedly be made to operate as now proposed, but it would be a desirable safeguard to adopt, to place screens above the entrance of the siphon, and thus prevent any large substances from getting into it. The satisfactory operation of the siphon would also be further insured by constructing an automatic flush tank above it, so that the sewage, instead of flow-

ing through it continuously in a sluggish stream, would pass through intermittently with a high velocity, and thus prevent the formation of putrefying deposits in the pipe. This intermittent discharge of the sewage would also facilitate its distribution over the land. The use of screens may be objected to on the ground that they will require excessive attention, but this objection can be overcome to a large extent by providing a very large screen area.

The changes as suggested would tend to decrease the cost of the work, as the screen chamber and flush tank should not cost any more than, if as much as, the proposed settling tank, sludge pipe and sludge bed; and by screening the sewage so that no large substances would enter the siphon pipe it would be feasible to reduce the diameter of this pipe to 8 inches.

With the present knowledge with regard to sewage disposal there would be a greater certainty of success if the sewage was discharged upon beds prepared upon the most porous part of the town land and disposed of by intermittent filtration. The proper preparation of these beds would include the removal of the black and yellow loam at the surface and the grading of the beds, so that the sewage could be evenly distributed upon them. It is probable, however, that, with the small quantity of sewage to be taken care of, satisfactory results may be obtained by the system of broad irrigation proposed by the town, and with less expense than by intermittent filtration, and the Board therefore thinks it proper that the town should begin to dispose of the sewage by broad irrigation. It would advise, however, that even in the beginning, several small beds, having an aggregate area of not less than one-half an acre, should be carefully prepared for intermittent filtration by the removal of the soil, for use at times when it is impracticable or inconvenient to dispose of the sewage by broad irrigation.

Where the sewage is disposed of upon a hillside by broad irrigation, there will be a tendency, if the sewage is allowed to flow long in one place, for it to gather in a stream and flow down the hill. To meet this contingency a large, level, intercepting ditch should be constructed around the lower part of the land, not less than 5 feet above the brook, to intercept streams of this character and prevent them from flowing unfiltered into the brook. Around other margins of the field small ditches should be dug to prevent the sewage from flowing off in these directions and convey it to the large intercepting ditch just mentioned.

In all cases of sewage disposal, and particularly where broad irrigation is adopted, the attainment of successful results depends to a very large extent upon the intelligent care taken to effect a proper distribution of the sewage.

**PITTSFIELD.** The city of Pittsfield presented to the Board, May 11, 1891, a plan of sewerage and sewage disposal, under the provisions of chapter 357, Acts of 1890, providing for the permanent disposal of sewage of the city by filtration upon land in the valley of the Housatonic River, with a temporary outlet into the river during the construction of the works. This plan was approved by the Board, May 12, 1891, with the provision that the direct discharge into the river should not continue after June 1, 1900.

On the 27th of December, 1892, the Sewer Commissioners applied to the Board requesting the following modification of the plan approved by the Board: "To strike out so much of said plan as designates specific areas of land for the permanent disposition of said sewage, and by striking out so much of said plan as provides that after the date therein specified all sewage is to be pumped to filtering fields across the river and there disposed of by intermittent filtration, and by inserting instead thereof a provision that after said date all sewage is to be permanently disposed of by such methods as the State Board of Health shall then approve." The Board replied to this application as follows:—

BOSTON, Jan. 10, 1893.

By the plan approved by the State Board of Health, above referred to, the Board permitted the use of the Housatonic River for the discharge of the sewage of Pittsfield until the year 1900, and after that date the sewage was to be cared for upon filtering areas of land and the discharge into the river stopped. The use of the river was therefore but for a brief period, and the main features of the general plan presented by the city of Pittsfield, and approved by this Board, provided for the ultimate care of the sewage upon the filtering areas. The changes now asked for, if approved by this Board, would leave the city of Pittsfield without provision for its future disposal of sewage other than the river. The Board is of opinion that such a course is not advisable for the city, nor does the Board feel it will do its duty should it approve any plan not fully providing for the future proper sanitary care of the city's sewage. The Board therefore cannot approve the amendments as proposed, but will consider any further plans in regard to the ultimate disposal of the sewage which the city may desire to present.

**PLYMOUTH.** The committee on sewerage of the town of Plymouth applied to the Board, March 30, 1893, for its advice

relative to a plan of sewerage and sewage disposal for that town. The Board replied as follows : —

Boston, June 14, 1893.

The plan referred to shows the outlines of a system of sewerage for the portion of the town from which sewage can be brought by marginal intercepting sewers to a point in Water Street just north of all wharves, and a 12-inch cast-iron pipe extending from this connecting point out into the harbor to the North Guzzle, so called. It is understood that the plan proposes the admission of storm water into the sewers from the main street of the town, but that elsewhere it is to be excluded. In order to provide for the disposal of the storm water, storm overflows from the marginal sewer are provided at four points along the shore.

The only important feature in which the Board advises a change is in the outlet pipe, which, in the opinion of the Board, should be changed so as to reach the Guzzle at a point as far from the shore as it is practicable to extend the pipe, but not more than 1,500 feet. The limit of 1,500 feet is mentioned because it is doubtful if a pipe longer than this could be kept free from deposits. In making the pipe longer, as advised, its size should be increased to 14 inches, which will not only offset the loss of capacity due to the greater friction of a longer pipe, but will also give a slight addition to the capacity, which is desirable.

The sizes and inclinations of the intercepting sewers appear to have been judiciously chosen, so far as can be judged from the preliminary plan submitted. These sewers of necessity are placed at a low level as compared with high tide, and have rather low grades, so that they may not prove wholly self-cleansing, but, even if they should not, the amount of care required to keep them clean would not be excessive. The cleaning of the southern branch of the intercepting sewer may be facilitated by the construction of an inlet as large as the sewer itself from the lower millpond on Town Brook, provided the millpond is at a sufficient elevation, this inlet to be used from time to time at low tide for flushing the sewer.

As a precaution against the clogging of the outlet pipe the Board would suggest the construction of a small chamber at its upper end, where it receives the sewage from the intercepting sewers. The bottom of this chamber should be depressed so as to act as a settling basin and catch any heavy material brought down by the sewers. It could be built in the street, but it would be better to construct it just outside the street lines and make it easily accessible. A gate at the upper end of the pipe, by which the water or

sewage could be held back in the sewers and then let out suddenly at low tide to flush the pipe, would be an advantage.

SPENCER. The superintendent of sewers of Spencer applied to the Board, June 1, 1893, for its advice relative to a system of sewage disposal upon land in the valley of Seven Mile River. The Board replied as follows : —

Boston, Dec. 8, 1893.

The Board finds from the statements contained in your application, and from the examinations made by one of its engineers, that the topography of the town is such that nearly all of the sewage can be collected by a system of sewers with a main sewer leading toward the Seven Mile River at a point south-westerly from the centre of the town, that the main sewer and a large part of the tributary sewers of this system have already been built, and that the sewage is now discharging into the river. It is the sewage from this main system which you propose to deal with at present.

The sewers already built are for the most part intended to take sewage only, but at a few points catch-basins have been built through which considerable storm water is admitted to the sewers ; and there is also a considerable amount of ground water finding its way into them, which materially increases the volume of sewage to be taken care of. The sewers also receive, in addition to the sewage proper, certain waste matters from the gas works in the town, which make the sewage particularly offensive and destroy the vegetation in the vicinity of the sewer outlet.

The town is situated on high land, and the main sewer falls rapidly until it reaches the lower land bordering the river. By intercepting the sewage before it reaches too low a level the sewage can be discharged by gravity upon land at a sufficient height above the river for sewage filtration. The suggestion has been made by you that the town now owns ten acres of gravelly land near the river, through which the present main sewer passes, which might be used for the disposal of sewage by intermittent filtration ; and that there are also about three acres of similar land adjoining the town lot on the south which might be used if additional area was required.

The material of the town lot, as determined by several test pits and by an examination of the surface of the ground, is of suitable quality for the disposal of sewage by the method suggested. The proper preparation of the lot for sewage disposal would involve the removal of the surface loam and the grading of the land into beds of suitable size, having a surface of porous sand or gravel.

In order to make the lower portions of the land available it would be necessary, after removing the surface loam, to raise them by filling with porous sand or gravel to a level six feet above ordinary high water in the river. The filter beds which have surfaces not more than 8 feet above the river should be underdrained. By taking the sand or gravel for this filling from the higher portions of the land and by building a few hundred feet of sewer in Main Street, so that the sewage will reach the lot at a higher level, it will be feasible to utilize all of the gravelly land, including the three acres lying south of the town lot.

It is desirable to restrict as far as practicable the amount of sewage to be taken care of, and in order to do this the surface water, which now enters the sewers through the catch basins in the streets should be disposed of in some other way. It is also desirable to diminish the amount of ground water, if, upon examination, it should be found feasible to do so. Should any large amount of ground water be found to enter the main sewer, or should it be found desirable to continue to dispose of the storm water through underground channels, it may be best to lay a new main sewer of much smaller size than the present one to take the sewage, reserving the present main sewer for the discharge of surface and ground water. The surface water which would naturally flow from adjacent high land upon the filter beds should also be collected and disposed of in such a way that it will not tend to saturate the beds. It may be feasible to turn this water into the lower portion of the present main sewer below the point where the sewage will be diverted from it to the filter beds.

It may be said, with regard to the disposal of the sewage of the town by intermittent filtration, that it is not probable that the results will be satisfactory unless the wastes from the gas works are excluded from the sewers, or, before being admitted, are treated in such a way as to make them inoffensive, and to remove all tarry or oily substances which would tend to clog the filter bed.

The area of suitable land at the town lot and the lot adjacent to it is smaller than is desirable, considering the large amount of ground water which finds its way into the sewers, and the increasing quantity of sewage which will enter the sewers as they are extended and the town increases in population. If the ground water could be excluded from the sewers, the area would be sufficient until the population of the town is considerably larger than at present.

In view of the somewhat limited area of land available at and near the town lot, examinations were made to determine whether additional land was available, and a tract was found, lying in a

south-westerly direction from the town lot, between the Brookfield road and the river, just beyond the cemetery, which appeared from a surface examination to be suitable for sewage filtration. This land is considerably higher than the river, but it is lower than the main sewer in Main Street, a short distance from the town lot, and the sewage could be conveyed to it through an iron pipe which would run full and under pressure. The lowest point in this pipe would be at the corner of Meadow and Main streets, nearly opposite the town lot, so that the pipe could be emptied frequently upon filter beds on the town lot, and thus kept clean. This tract of land is of suitable quality, and probably other land in this vicinity could be made available for the disposal of sewage.

While the town lot has a decided advantage, owing to its present ownership by the town and the ease with which sewage can be turned upon it, it will obviously be quite expensive to grade it and the small lot south of it so that the whole area of these lots will be available for sewage disposal, and unless the amount of sewage is materially diminished by the exclusion of ground water, it will be necessary to provide additional filtering area before long. It is therefore recommended that the town lot should not be finally adopted as the only site for filter beds until the other tract of land beyond the cemetery has been more carefully investigated, by digging test pits to ascertain if the material is porous and suitable for filtration; and, if so, whether it will not be cheaper to prepare the required area of filter beds partly at the town lot and partly at the lot beyond the cemetery; or, if not cheaper, whether it may not be desirable to control this second lot from the beginning, so as to have an opportunity to extend the filter-beds whenever it becomes necessary.

When you have the results of further surveys and estimates, or more definite plans of sewage disposal to submit, the Board will advise you further in this matter.

The Board is of the opinion that the discharge of the sewage directly into the Seven Mile River should be discontinued.

**WESTBOROUGH.** The committee on sewerage of the town of Westborough presented a general plan for the sewage disposal of the town, Feb. 3, 1890, which the Board approved (Senate Document 4, 1891, page 18). By a general Act of the Legislature of 1890, chap. 124, it was provided that land might be taken for sewage disposal with the approval of the State Board of Health after a public hearing. Under the provisions of this Act the selectmen applied to the Board

June 22, 1891. A hearing was held July 7, 1891, and the location submitted by the town was approved by the Board, July 8, 1891 (Senate Document 4, 1892, page 49).

In the following year, April 16, 1892, the selectmen of Westborough presented a plan, which, after due consideration, the Board deemed unsatisfactory and expressed such opinion in a communication to the selectmen, Nov. 3, 1892 (Senate Document 4, 1893, page 6), stating the conditions essential to success.

The selectmen again applied to the Board, Sept. 18, 1893, stating that the advice of the Board had not been carried out, and requesting the Board to "make an examination of the present sewage-disposal works of Westborough and advise the town further in the matter of sewage disposal." The Board replied as follows:—

BOSTON, Oct. 26, 1893.

In compliance with this request the Board has caused an examination of your present works to be made by one of its engineers. He finds that you have prepared filter-beds, having an area of a little more than two acres, by filling porous sand and gravel to a depth of from one to two and a half feet upon land from which the greater part if not all of the loam had been removed. From an examination by means of test pits dug at various points in the filter beds, he finds that the material beneath the upper porous layer is an extremely fine sand which not only remains saturated with water, but also keeps the porous material above it saturated for weeks after the discharge of sewage upon it has ceased. These conditions are unsuitable for the purification of sewage; and a very small quantity of sewage only could be disposed of upon these shallow beds if they were underdrained.

It was also found that a portion of the sewage was disposed of by being turned into a gravel pit, near the carrier, until the sewage stood in the pit to a depth of several feet, when it filtered into the ground quite rapidly, and the water reappeared in the form of a spring, a short distance away, clear but not thoroughly purified. It is highly improbable that this method of disposal would continue to give even as good results as at present for any long time in the future if any large proportion of the sewage should be turned into this pit. The rapidity with which the sewage disappears shows that the ground is porous in this vicinity, and that a good filter-bed might be prepared here which would successfully dispose of a portion of the sewage.

In reply to a previous application made by your board, the State

Board of Health sent to you on Nov. 3, 1892, a communication containing its advice in a general way as to what the town should do to properly dispose of its sewage. This advice, which the Board has no reason to modify, is as follows : —

The Board . . . . advises that the town should prepare filter-beds having a total area of not less than five acres for the disposal of its sewage. These beds should consist of sufficiently porous material to properly filter the sewage, and if of such a character or so situated that the ground-water level will not remain at least five feet below the surface of the beds, they should be efficiently underdrained.

The most economical method of preparing beds such as are here described is a matter which requires investigation. If a portion of your land can be found where there are two or three feet of porous material above the level of the water in the Assabet River, the required height of filter-bed can be obtained by filling gravel upon this portion after the loam or any other layer of very fine material which may be found has been stripped from it. If such land as is here described cannot be found, it may then be necessary to prepare beds by cutting down some of the higher gravelly land to the proper level, and filling the excavated material upon the low land, both the excavated and filled areas being used for filtration. The character of the material lying on the easterly side of a narrow swamp, and also easterly from the tract belonging to the town, appears to be of suitable quality for the construction of filter-beds by the last described method.

The Board cannot give you any more specific advice than that above given as to what should be done, because it is not feasible from such examinations as are made by its engineers to obtain the accurate data upon which such advice should be based in order to avoid wasteful expenditures and unsatisfactory results.

What you should therefore do is to employ some engineer skilled in this class of work to make plans of all the territory which may be used for sewage disposal, showing the height of the ground, the level of the water in the ground and the location of the test pits, which should be sunk at frequent intervals and to a sufficient depth to determine accurately the character of the material at different places with reference to its porosity. He should also determine where and how filter-beds can be constructed at a minimum cost, which will at least meet the requirements contained in the former reply of the Board.

If you should decide to make such investigations the Board will direct its engineers to co-operate with your engineer in the matter of determining the suitability of materials obtained from test pits for filtering sewage; and when the investigation is far enough advanced and new plans are presented the Board will advise you further regarding them.

Odor, none; on heating, the first two samples had a faintly vegetable odor. — The samples were collected as follows: No. 15784, from Fort Pond, about 30 feet from the shore at the southerly end; No. 15785, from Magog Brook, about 50 feet above the road leading from Acton Centre to North Acton and about one mile below Magog Pond; No. 15786, from Magog Pond, near the road at the easterly end.

*Microscopical Examination.*

The total number of organisms per cubic centimeter found in each of these samples was as follows: No. 15784, 123; No. 15785, 43; No. 15786, 41.

# EXAMINATION OF WATER SUPPLIES.

---

## EXPLANATORY NOTE.

The systematic examination of the water supplies of the State was begun June 1, 1887, and has been continued up to the present time. The results for the years previous to 1893 have been published in four reports, as follows: June 1, 1887, to May 31, 1889, in the Special Report of the Board upon the Examination of Water Supplies (1890); June 1, 1889, to Dec. 31, 1890, in the Twenty-second Annual Report of the Board for the year 1890; for the years 1891 and 1892, in the Twenty-third and Twenty-fourth Annual Reports of the Board for those years. The present (Twenty-fifth Annual) report contains the results for the year 1893.

The first of these reports contained a description of each of the water supplies in the State existing at the date of that report. The later reports have described only new works and changes in existing works.

An alphabetical arrangement by towns has been adopted in this, as in previous reports. Sources of water supply are tabulated under the name of the town supplied, other waters under the name of the town in which they are situated. The analyses of water from the larger rivers not used as sources of water supply are given in a subsequent tabulation, headed "Examination of Rivers."

The chemical examinations in this report were made in the same manner as heretofore, and are presented in the tables in the same form as in the last report, except that a new determination, "Oxygen Consumed," has been added. This determination has been made for all waters this year, and appears in the tables of analyses for the first time. Owing to the space occupied by the column of "Oxygen Consumed," the "date of examination" of the samples has been omitted from the tables. The samples are usually received at the laboratory from twenty-four to forty-eight hours after collection.

All surface water and such samples of ground water as contain suspended matter are filtered through filter-paper before determining the color, the residue on evaporation and the albuminoid ammonia in solution. Some ground waters which are perfectly clear and colorless when drawn from the ground become turbid and colored on standing, in consequence of the oxidation of the iron which they contain. In these waters the residue on evaporation is determined without filtration, since this iron is an essential and not an accidental ingredient in the water. In the changes which accompany the oxidation of the iron in waters of this character, they become first cloudy (well described by the word *milky*) and finally deposit a precipitate of oxide of iron. In the cloudy condition they have a distinct color, which, while it does not have the same significance as in the case of surface waters and is only a passing phenomenon, is, nevertheless, of interest as showing a color which the water may assume while the oxidation of

the iron is in progress. When the iron is all oxidized and precipitated the water may become colorless again. Explanatory notes will be given for waters of this kind in connection with the tables of analyses.

The color of water is expressed by numbers which increase with the amount of color. The standard used is nesslerized ammonia, as described on page 531 of the Special Report upon the Examination of Water Supplies, 1890, and on page 329 of the Annual Report for 1893. Boston water, as drawn from a tap at the Institute of Technology, has had an average color for six years of 0.43. Other water supplies in the State have had an average color of from 0 to 1.45.

In cases where examinations of a source have been made with considerable regularity for several years, the averages of the results of the chemical analyses of previous years are appended to the tables of analyses for 1893.

In the microscopical examination of water there has been no change in the method employed since Nov. 6, 1890. This method was fully described in the Twenty-third Annual Report of the Board for the year 1891 (pages 395-421). Before Nov. 6, 1890, the methods employed were less perfect, so that a smaller proportion of the total number of organisms present in the water was separated from it and observed under the microscope; and, before drawing conclusions from a comparison of the microscopical examinations of waters made before and after this date, the explanatory note on page 70 of the Twenty-second Annual Report for 1890 should be read.

To indicate the amount of the so-called *Zoöglæa* observed, the number of individual masses is not counted, but an area equal to 2,500 square microns, or .0025 square millimeters, has been adopted as an arbitrary unit.

In publishing the results of the microscopical examinations the same system is followed as last year. The plants observed are classified in four groups, viz.: Diatomaceæ, Cyanophyceæ, Algæ and Fungi. The Animals observed are grouped as Rhizopoda, Infusoria, Vermes and Crustacea.

The names of the different genera in each group are given with the numbers of each per cubic centimeter, except that, to avoid making the tables excessively long, they are omitted when present only in very small numbers. It is not feasible to make with regard to omissions a single rule which will apply to all cases, because it is desirable to include smaller numbers of animals than of plants, and of the larger animals than of animals generally. Moreover, there are exceptional cases in which it is desirable to indicate the presence of even very small numbers of the more important plants or animals. Two general rules, however, have been adopted in printing the results, namely:—

1. All genera of Plants are included in which the total number observed in twelve months amounts to 6 or more per cubic centimeter, or in other words averages as much as 0.5 per month.

2. All genera of Animals are included in which the total number observed in 12 months amounts to 1.5 or more per cubic centimeter.

The larger microscopic animals, such as some of the Crustacea, are included, even when present only in very small numbers.

Fractions are generally omitted from the table, the nearest whole number of organisms per cubic centimeter being given. Where the total number of organisms observed is 0.5 or less, the fact that the organism was present is usually indicated by the abbreviation "pr.," but in the case of the larger organisms very small fractions are given.

## WATER SUPPLY OF ARLINGTON.

The advice of the State Board of Health to the town of Arlington relative to obtaining an additional water supply for the town and improving the quality of the present supply may be found on pages 9-12 of this volume. For analyses of samples of water from the wells mentioned in the reply to the town see the twenty-fourth annual report for 1892, pages 81-82. Additional analyses of water from these wells were made in 1893, and are given in this report on page 97.

Iron, .0149. Odor, vegetable or none; often becoming stronger on heating. — Water from this brook is drawn into the filter-gallery beside the reservoir and is thence supplied directly to the town, making it unnecessary to draw water from the reservoir except at times when the supply from the brook and filter-gallery combined is insufficient for the use of the town.

*Microscopical Examination.*

Average number of organisms, 177. The greatest number in any sample was 734 in March, consisting almost entirely of *Oreothrix* and *Zoëglæa*.

Odor of the first sample, none; of the second, none, becoming faintly vegetable on heating; of the last, very faintly vegetable, disappearing on heating. — The samples were collected during a pumping test from the same tubular wells that were tested last year. The test was begun on December 1, and pumping was continued at an average rate of 384 gallons per minute from 17 wells until after the second sample was collected. The third sample was collected while pumping from 13 wells at a rate of 287 gallons per minute.

## WATER SUPPLY OF ATTLEBOROUGH.

In April, 1892, the town of Attleborough introduced water from a new source and abandoned its former source of supply near the Ten Mile River, in the thickly settled portion of the village.

The new source of supply is a large well about one hundred and fifty feet from Seven Mile River, just above Orr's Pond, — a mill pond at the confluence of Seven Mile River and Four Mile Brook. The well is thirty feet in diameter at the top and twenty-five feet deep. For the first five feet the material removed was a coarse compact gravel of a reddish tint. Beneath this was a stratum from two to six inches in thickness consisting of particles of coarse sand closely cemented together, and having a color somewhat resembling iron rust. Below this stratum to the bottom of the well, twenty-five feet beneath the surface, the material was a coarse sandy gravel in which no quicksand or very fine sand was found, and no stones of a greater diameter than eight inches. At the bottom of the well the material was very coarse.

A tubular well one and one-fourth inches in diameter was driven to a farther depth of twenty-five feet below the bottom of the well, without striking rock.

The walls of the well are of stone for a height of ten feet above the bottom, the first eight feet being laid without mortar. Above the stone work the walls are of brick masonry sixteen inches in thickness for a height of eight feet and twelve inches in thickness for the remaining ten feet, bringing the top of the wall about three

**ATTLEBOROUGH.**

feet above the surface of the ground. Light is excluded from the well by a wooden roof. A direct connection has been made with Orr's Pond for use in cases of emergency. Water is pumped from the well to the distributing system and to a covered iron tank.

During construction this well is said to have yielded water very freely.

Odor of all samples, vegetable. — The samples were collected as follows:—No. 11,540, from Emerson Brook at the saw mill dam in Uxbridge about half a mile above the point where the brook is crossed by the New York and New England Railroad. No. 11,541, from Angelica Brook just above the point where it is crossed by the New York and New England Railroad; this brook is a small stream which enters the Blackstone River from the south just below the village of Millville in Blackstone. No. 11,542, from Ironstone Brook just above the point where it enters the lower Ironstone Reservoir; No. 11,543 from the upper Ironstone Reservoir in the vicinity of the boundary line between Massachusetts and Rhode Island. The samples were collected during an investigation for a water supply for the town of Blackstone.

*Microscopical Examination.*

The number of organisms per cubic centimeter found in each sample was as follows: No. 11,540, 46; No. 11,541, 24; No. 11,542, 21; No. 11,543, 18.

## BOSTON.

## WATER SUPPLY OF BOSTON.

The principal change in the conditions affecting the character of the Boston water supply during 1893, is the filtration of the water of Pegan Brook through carefully prepared filter-beds of large area before it is discharged into Lake Cochituate. This brook drains the central portion of the town of Natick, which has no sewerage system.

The extension and increased use of the sewerage systems in Framingham, Marlborough and Westborough, has caused a still greater proportion of the sewage of these towns to be removed from the watershed of the Sudbury River than was the case last year.

The works of the Jamaica Pond Aqueduct Company were purchased by the city of Boston at the end of 1892, and the supply from this source has been permanently discontinued.

SUDBURY RIVER SUPPLY.—*Chemical Examination of Water from Cold Spring Brook, at Head of Reservoir No. 4, Ashland.*

\* June to December.

NOTE to analyses of 1893; Iron, .0118. Odor generally faintly vegetable, sometimes none; on heating the odor is generally somewhat stronger, but rarely unpleasant. The samples were collected from the reservoir near the gate-house one foot beneath the surface. — The surface of the water in this reservoir was from 18 to 21 feet below high water mark in January and during the next two months rose practically to high water mark, at which point it remained until August. On September first the water had been drawn down 14 feet below high water mark and during the remainder of the year on dates when samples of water were collected for analysis the reservoir never contained more than 9 feet of water and at the first of December was empty. For monthly record of height of water in this reservoir see table at end of Boston analyses.

\* June to December.

NOTE to analyses of 1893, Iron, .0166. Odor, generally vegetable, occasionally mouldy or unpleasant, becoming somewhat stronger on heating. — The samples were collected from the river near the old dam at the upper end of Reservoir No. 2, at a depth of one foot beneath the surface.

*Microscopical Examination.*

Average number of organisms in 1893, 157 per cubic centimeter. The greatest numbers found were 738 in January, consisting chiefly of Zoöglæa and Diatomacæ, and 282 in November, chiefly Diatomacæ.

\* June to December.

NOTE to analyses of 1893; Iron, .0139. Odor, generally distinctly vegetable, occasionally unpleasant, becoming somewhat stronger on heating. — The samples were collected from the reservoir near the gate-house, at a depth of eight feet beneath the surface. For monthly record of height of water in this reservoir see table at end of Boston analyses.

Iron, .0278. Odor, generally distinctly mouldy or musty, occasionally offensive. On heating, the odor becomes somewhat stronger. — The samples were collected from the brook at the first road bridge below Maple Street, about a mile south of the centre of the city of Marlborough.

This series of analyses is being made in order to determine to what extent the pollution of the brook will be diminished by the introduction of a sewerage system into the city of Marlborough. The system was put in operation in the latter part of 1891.

\* June to December.

NOTE to analyses of 1893; Iron, .0172. Odor, generally distinctly vegetable, frequently mouldy or unpleasant; on heating, the odor is stronger and frequently grassy.—The samples were collected from the brook about 50 feet below the first road above Reservoir No. 3, at a depth of one foot beneath the surface.

*Microscopical Examination.*

Average number of organisms in 1893, 123 per cubic centimeter. In September, when the organisms were most abundant, 302 were found, nearly all of which were *Crenothrix*.

\* June to December.

**NOTE** to analyses of 1893; Iron, .0178. Odor, generally distinctly vegetable. On heating the odor is stronger and frequently unpleasant or disagreeable.—The samples were collected from the reservoir near the gate-house at a depth of eight feet beneath the surface. For monthly record of height of water in this reservoir see table at end of Boston analyses.

\* April to December.

NOTE to analyses of 1895: Odor, generally distinctly vegetable and occasionally unpleasant. The iron was determined in seven samples, the average amount in parts per 100,000 being .0216. — The samples were collected from the reservoir near the dam.

\* June to December.

NOTE to analyses of 1895: Odor, vegetable. — The samples were collected from the brook at its entrance into Reservoir No. 4.

*Microscopical Examination.*

The average number of organisms per cubic centimeter found in these samples was 68.

Iron, in the first sample, .0080; in the second, none; in the third, .0020; in the last, .0770.

Odor of the first sample, faintly disagreeable, becoming stronger on heating; of the next two samples, very faint or none; of the last sample, offensive. — The first sample was collected at the surface, and the others in order at depths of 20, 54 and 74 feet respectively beneath the surface.

The reservoirs on Sudbury River were drawn to an unusually low level in 1893. Reservoir No. 2 in December contained 116,500,000 gallons equal to 22 per cent. of its total capacity; Reservoir No. 3 in November contained 62,000,000 gallons equal to 5.6 per cent. of its total capacity; Reservoir No. 4 in December was practically empty, containing only 11,000,000 gallons, equal to less than one per cent. of its total capacity.

## BRADFORD.

to the water are at first so very fine that they communicate to the water a milky appearance which cannot be removed by filtration, and the effect of it is to make the water appear colored as if from dissolved coloring matter. When the oxidation of the iron is complete, a rusty precipitate usually forms and the supernatant or filtered water is again clear and colorless. Any record of turbidity, sediment or color, while the oxidation of the iron is in progress, relates, therefore, to a passing phenomenon, but is nevertheless of interest as showing a condition which the water may assume; these records cannot, however, be considered as indicating the comparative character of the water from month to month, because they depend so largely upon the extent of the oxidation of the iron at the time they were made. The presence of iron affects the determination of the "oxygen consumed," and the results of this determination as given in the tables are in consequence all a little higher than they would otherwise be. A progressive deterioration of this water, as compared with previous years, will be noted. The organic matter, as shown by the albuminoid ammonia, and the product of its decomposition, as shown by the free ammonia, are decidedly on the increase.

\* June, 1887, to May, 1888.

NOTE to analyses of 1893; Odor, of No. 10102, faintly vegetable; of the others, none. On heating a very faintly vegetable odor was developed in No. 10232. — The samples were collected from a faucet at the pumping station.

*Microscopical Examination*

No. 9848. Diatomaceæ, *Tabellaria*, 62; Nos. 10495 and 10608, Cyanophyceæ, *Anabæna*, 5 in the first, and one in the last; Nos. 10495 to 11157 inclusive each contained a few *Crenothrix* or *Zoëglia*. In the remaining samples no organisms were found.

Iron, .0045. Odor, faintly vegetable, becoming stronger in the last two samples on heating. — The samples were collected from the pond near the filter-gallery of the Braintree water works, which is situated on the shore of the pond. It is said that up to the end of 1893, no water had been drawn directly from the pond for the supply of the town.

*Microscopical Examination.*

The total number of organisms per cubic centimeter found in each of these samples was as follows: In May, 93, chiefly *Diatomacea*; in August, 1893, chiefly *Alga*; in September, 93, chiefly *Alga* and *Cyanophyceae*.

## WATER SUPPLY OF BRIDGEWATER AND EAST BRIDGEWATER. — THE BRIDGEWATERS WATER CO.

In 1892, the works of this company for collecting ground water were again enlarged by sinking five additional six-inch tubular wells in the low ground between the present works and the river. The new wells are located in a line parallel to the river, and are said to range from 100 to 160 feet in depth. Water is pumped from these wells by means of an auxiliary pump into one of the large wells near the pumping station.

Iron, .0275. Odor, distinctly vegetable, becoming stronger on heating, and sometimes also mouldy. — The samples were collected from the river opposite the works of the Bridgewaters Water Company.

*Microscopical Examination.*

The total number of organisms per cubic centimeter found in each of these samples was as follows: In June, 133; in July, 144; in August, 2,651; in September, 83. The numbers consisted almost wholly of *Crenothrix* and *Zoëglæa*.

## WATER SUPPLY OF BROCKTON.

*Chemical Examination of Water from Salisbury Brook at the Point where it enters the Storage Reservoir of the Brockton Water Works.*

[Parts per 100,000.]

\* In addition to the analyses of water from this reservoir given here, the results of examinations of three samples of water collected from various depths under the ice on March 15, 1893, may be found in the annual report of this Board for 1892, page 340. The additional analyses were made as a part of an investigation to learn the quantity of dissolved oxygen in water under the ice.

† June to December.

NOTE to analyses of 1893; Iron, .0157. Odor generally distinctly vegetable, and very frequently disagreeable. On heating, the odor usually becomes somewhat stronger, and in January and February was very disagreeable. — The samples were collected from the reservoir near the gate-house at a depth of one foot beneath the surface. For a record of heights of water in this reservoir on dates when samples of water were collected for analysis see page 129.

The table of averages shows that there has been a marked decrease in the amount of albuminoid ammonia in this water since the examinations were begun in 1887, indicating a corresponding improvement in its quality. An examination of the monthly analyses during this time, shows that during the earlier years there was a large fluctuation in the amount of albuminoid ammonia in the different seasons of the year, the greatest quantities being found in the summer and early autumn, when abundant growths of microscopic organisms were present in the water. The decrease in the amount of albuminoid ammonia, as shown in the table of averages, is due chiefly to the decrease in the growths of these organisms in summer.

*Aeration.*

Provision was made in the year 1891 for aerating the water supplied to the city of Brockton by forcing air into it through a system of perforated pipes laid near the bottom of the iron tank, as described in the Annual Report of this Board for 1892, page 110. The tank is 62 feet in diameter and 59 feet 4 inches in height, and is open at the top. In the following table is given a comparison of analyses of samples of water collected as it comes from the reservoir and after aeration in the tank.

Iron, .0420. Odor, faintly vegetable. — The sample was collected from the underdrain at a man-hole near the Salisbury Plain River south of Perkins Avenue.

The sewerage system of the City of Brockton had not been completed at the time this sample was collected and no sewage had been admitted to the sewers. The sample therefore indicates the average character of the ground water of the region through which the sewer passes.

Odor, none; becoming faintly vegetable on heating. The sample was collected from a hydrant. The source of supply is a storage reservoir located upon a small brook. This is not a representative sample of the water as it enters the pipes from the reservoir.

**WATER SUPPLY OF BROOKLINE.**

An important addition was made to the Brookline Water Works in 1893 by the completion of a covered distributing reservoir, which resembles in its general design the covered reservoir constructed by the city of Newton in 1890 and described in the twenty-third annual report of this Board for 1891, page 185. The new reservoir is a rectangular chamber ninety-three feet four inches long, ninety-one feet four inches wide and nineteen and one-half feet deep. The walls are of rubble masonry, coated on the inside with a layer of Portland cement mortar, one-half an inch in thickness. The covering consists of four-inch brick arches, supported on lines of brick piers connected by brick lintel arches, the outer edges bearing on the surrounding walls. The piers are twenty-four inches square and twelve and one-half feet apart on centers. The bottom of the reservoir is formed of a layer of clay puddle two inches in thickness, over which is a layer of cement concrete four inches in thickness. The arches are covered with Portland cement concrete to a level four inches above their crown, and over all is a layer of loam eighteen inches in thickness. Tile drains four inches in diameter are laid beneath the loam in grooves in the concrete to carry off the

**BROOKLINE.**

surplus rain-water. At the top of each line of arches is located a ventilator to allow a free circulation of air.

Water enters the reservoir near the bottom through a cast-iron main twenty inches in diameter, and is drawn out through the same pipe. Provision was made for drawing all the water out of the reservoir if necessary by giving the bottom a slight slope toward a gutter, the bottom of which also has a slight slope and conveys the water to a ten-inch pipe passing through the wall. The reservoir is provided with an overflow 16.2 feet above its bottom, and surplus water flows off in this way into the open distributing reservoir near by. The open reservoir is still retained for use in cases of emergency.

Water is now delivered to consumers without exposure to light at any point, and it is said that since the new reservoir was put in operation the consumers have been very well satisfied with the character of the water, and all complaints of bad tastes and odors have ceased.

*Chemical Examination of Water from a Faucet at the Low Service Pumping Station and from the Covered Reservoir of the Brookline Water Works.*

\* June to December.

NOTE in analyses of 1890: Iron, .0110. Odor, generally vegetable, often none. On heating, the odor was generally somewhat stronger, and none of the samples were odorous. — The samples were collected from the pump well at the pumping station. For a record of heights of water in this pond at times when samples of water were collected for analysis see page 126.

It will be noticed from an examination of the averages of analyses of previous years, that there has been a decrease from year to year in the amounts of solids and chlorine in the water of this pond since the examinations were begun, accompanied by a general though not regular increase in color. These changes are due to the introduction of water from Stony Brook into Fresh Pond, which began early in November, 1897, at a time when the water in Fresh Pond was very low. The quantity of water turned into the pond from the brook increases from year to year with the rapidly increasing consumption of water in Cambridge, and the character of the water in the pond is consequently approaching that of the water in the brook.

## CAMBRIDGE.

*Microscopical Examination of Water from Fresh Pond, Cambridge.*

[Number of organisms per cubic centimeter.]

\* June to November.

NOTE to analyses of 1893; Iron, .0149. Odor, generally distinctly vegetable, rarely unpleasant. On heating the odor often becomes stronger, and sometimes disagreeable. — The samples were collected from the reservoir near the surface at the dam. For heights of water in this reservoir at times when samples of water were collected for analysis see page 136.

## WATER SUPPLY OF CANTON.

The advice of the State Board of Health to the town of Canton relative to a proposed additional water supply from the valley of Beaver Brook above the present pumping station of the Canton Water Works, may be found on pages 14 and 15 of this volume. In the following table is given the analyses of samples of water collected in connection with the investigation for this additional water supply.

*Chemical Examination of Water from Tubular Test Wells, in the Valley of Beaver Brook, Canton.*

\* This sample when received at the laboratory had a color of 0.70 caused by minute particles of iron rust in suspension, but subsequently, after the iron rust had precipitated, became nearly colorless.

Odor, of No. 9923, faint; of the others, none. — Sample No. 9922 was collected from tubular test well No. 2, 20 feet deep, driven through 11 feet of muck and five feet of sand into gravel. No. 9923, from test well No. 3, 20 5 feet deep, driven through 1.45 feet of muck and 2 feet of fine sand into gravel. No. 9957, from test well No. 5, 20 feet deep, driven through 5 feet of muck and 5 feet of fine sand into gravel. Water was pumped from the wells with a hand pump before collecting the samples, for periods varying from 2 to 4½ hours. The wells were located in the vicinity of Beaver Brook, at a point where it is joined by a small branch from the south, about half a mile above the pumping station of the Canton Water Works.

## Microscopical Examination.

No organisms.

## CHELSEA.

## WATER SUPPLY OF CHELSEA.

(See *Boston, Mystic Works.*)

## WATER SUPPLY OF CHESTER.

*Description of Works.* — The population of the town in 1890 was 1,295. The population of the main village, which is the only portion of the town supplied with water, is said to be about 800. The works are owned by C. L. Goodhue. Water was introduced in November, 1893, and was supplied to about 60 families at the end of the year.

The source of supply is Austin Brook, a tributary of Walker Brook. Water is drawn from Austin Brook at a point about 1,200 feet from its mouth, and less than a mile west of the village of Chester, where a small reservoir has been constructed at a sufficient elevation to supply the town by gravity. It is said that the reservoir is formed by a dam about 8 feet in height, and covers an area 60x80 feet to an average depth of about 6 feet.

The brook, above the point where the dam is located, drains an area about  $1\frac{1}{4}$  square miles, which is mainly pasture and woodland; it is said that there is but one dwelling house on this area.

The distributing mains are of cast-iron, and the service pipes are of galvanized iron.

The advice of the State Board of Health to the town of Chester, with reference to taking a supply of water from Austin and other brooks, may be found on pages 15 to 17 of this volume.

*Chemical Examination of Water from Austin, Blandford and Walker Brooks, and Horn Pond in Chester and Becket.*

Iron, in No. 10430, .0060; in No. 10431, .0025; in the remaining samples, none. Odor of the first two samples, none; of the third, distinctly vegetable, disappearing on heating; of the last, very faintly vegetable. — The first sample was collected from Austin Brook; the second, from Blandford Brook, about a third of a mile from its mouth; the third, from Walker Brook, about a mile from the Chester railroad station, and the last from Horn Pond.

*Microscopical Examination.*

The number of organisms per cubic centimeter in these samples was as follows: No. 10430, 1; No. 10431, 9; No. 10433, not examined; No. 10432, 45.

## CHICOPEE.

## WATER SUPPLY OF CHICOPEE.

Until 1893 the city of Chicopee had been supplied with water from various sources as follows :—

Chicopee Centre, having a population in 1890 of about 7,500, was supplied with water by the Chicopee Water Company from Dingle Brook, and from wells, partly by gravity and partly by pumping.

Chicopee Falls (population in 1890, 5,553) was supplied chiefly from works owned by the district, with water pumped by the Chicopee Manufacturing Company from the Chicopee River within the village.

Willimansett Village (population in 1890, about 300) was supplied by the Willimansett Aqueduct Company with water by gravity from a small brook.

In 1892 the city of Chicopee acquired possession of the works of the Chicopee Water Company and of the Willimansett Aqueduct Company.

In the winter and early spring of 1892 there was a mild epidemic of typhoid fever in Chicopee Falls, and the State Board of Health, after investigation,\* found reason to believe that the epidemic was due to the use of water from the Chicopee River, a stream which receives the sewage of several thousand people, and taking these results in connection with investigations in other places showing that a polluted running stream is a very dangerous source of water supply, advised the city to secure a pure water supply for Chicopee Falls and to discontinue the use of river water. The new supply was completed at the end of 1893, and the use of water from the Chicopee River was discontinued.

*Description of Works.*—The new sources of supply are Morton and Cooley Brooks, the waters of which are taken near their confluence, about  $1\frac{1}{2}$  miles northeast of Chicopee Falls. Cooley Brook is a tributary of the Chicopee River from the north, and a large part of its course is through a ravine in the great sandy plain between Chicopee and Granby. Owing to the character of its watershed, which allows much of the water falling upon it to pass into the ground and move gradually toward the brook, which it finally reaches in the form of springs, its flow is well maintained in a dry

---

\* See "An Investigation of an Outbreak of Typhoid Fever in Chicopee Falls apparently due to infected Water Supply," made under the direction of Prof. W. T. Sedgwick in the twenty-fourth annual report of the State Board of Health for 1892, pages 705-714.

## CHICOPEE.

season. A dam about 170 feet long and 10 feet in height has been constructed across the brook at a point about three-fourths of a mile from its mouth, forming a small reservoir said to have a capacity when full of 5,500,000 gallons. All the loam and vegetable matter was removed from the area to be flowed up to the level at which it is proposed to hold the water, which for the present will be only high enough to divert the water into a conduit leading to the pumping station.

Morton Brook is a small branch of Cooley Brook, fed almost wholly by springs, which enters the latter a short distance below the dam just described. A low dam has been constructed across this brook a short distance above its mouth, forming a small reservoir about 80 feet long, 40 feet wide, and averaging three feet in depth, which was thoroughly cleaned.

A cast-iron conduit pipe 16 inches in diameter conveys water by gravity from Cooley Brook to a receiving basin at the pumping station, a distance of 2,434 feet. A branch conduit 8 inches in diameter, also of cast-iron, conveys the water from Morton Brook to the main conduit, a distance of 750 feet. It is proposed to take the supply as far as possible from Morton Brook, because of the better quality of its water.

The receiving basin is 107 feet long, 77 feet wide and 8 feet deep at high water. It is oval in shape, with sloping sides, and has a capacity of 350,000 gallons. The slopes are paved with bricks laid in cement, and the bottom is covered with a layer of Portland cement concrete, 6 inches in thickness, over which is a layer of gravel 4 inches in thickness. At the end of the basin where the conduit enters, there is a sand chamber 9 feet long, 6 feet wide and 8 feet deep, designed to catch heavy suspended matter, and from this chamber the water overflows into the main portion of the basin. The surplus water brought to the basin passes off through an overflow formed by a 20-inch pipe set perpendicularly in the centre of the basin, and discharging into a pipe leading to Cooley Brook.

Water is pumped from the basin to the city and to an open iron tank 55 feet in diameter and 60 feet in height, situated a short distance from the main pipe between the pumping station and the city. All new distributing mains are of cast-iron ; new service pipes are of galvanized iron and lead.

**CHICOPEE.**

The old works of the Chicopee Water Company will still be used as a low-service supply for the lower portion of the city.

The water supply of the village of Willimansett was introduced in the summer of 1892. The source of supply is a small brook, a tributary of the Connecticut River from the east, which flows from the westerly side of the great sandy plain already mentioned. A dam about 10 feet in height has been constructed across the brook, forming a small reservoir at a point where the elevation is sufficient to supply the village by gravity. Distributing mains are of cast-iron. Service pipes are of galvanized iron and lead.

\* This sample was turbid when received and the color was determined after filtration.

† June to December.

‡ January to May.

§ February.

NOTE to analyses of 1893: Odor, none. — The samples were collected from a faucet in the pumping station while pumping.

This water is beginning to show some of the characteristics of an "iron" water, namely, a noticeable turbidity, sediment and color, and the presence of iron and of certain microscopic organisms often found in such waters. The determinations of turbidity, sediment and color in a sample of water of this class vary with the length of time that the water has been exposed to the air after it has been drawn from the ground, since they are dependent upon the amount of iron which has been thereby oxidized and converted into an insoluble form. When the iron is all precipitated out, the water

**COHASSET.**

resumes its original appearance, free from color and turbidity. These results of turbidity, sediment and color are, therefore, only of value as showing a condition which the water may assume, and should not be used for making comparisons between the different samples.

## DANVERS.

## WATER SUPPLY OF DANVERS.

In the act of the legislature giving the town of Danvers the right to supply itself with water, the town was granted permission to take its supply from Middleton Pond, in Middleton, and Swan's Pond, in North Reading. The latter is situated a little less than half a mile from Middleton Pond and its surface is about twenty-two feet higher. Water was introduced from Middleton Pond in 1876, but the works were not extended to Swan's Pond until 1893, when a connection between the two ponds was made by laying a six-inch cast-iron pipe. Swan's Pond is said to have an area of about forty-five acres.

## WATER SUPPLY OF EAST BRIDGEWATER.

(See *Bridgewater*.)

## WATER SUPPLY OF EASTHAMPTON.

Works for taking a water supply from a new source were built by the town in 1892, and the use of water from Williston Pond has been discontinued. The new source of supply is Bassett Brook, a stream which rises in Northampton and flows into the Manhan River, just opposite the village of Easthampton. Water is taken from the brook a little less than a mile from its mouth, at a point where a low dam has been constructed forming a small basin. From the basin water flows by gravity, through a cast-iron pipe twelve inches in diameter, to a pumping station located at a dam on the Manhan River, a short distance below the mouth of Bassett Brook. From this point the water is pumped by water

**EASTHAMPTON.**

power, through a new cast-iron force main ten inches in diameter and one thousand two hundred and fifty feet in length, into the old system of distributing pipes in the village, the surplus water going to the distributing reservoir on Mt. Tom.

Bassett Brook, above the point of diversion, drains an area of about 6.9 square miles. In the upper portion of the watershed the slopes are steep, but in the middle and lower portions the surface is more nearly level, and there are considerable areas of flat land in the vicinity of the stream, some of which are swampy. There are no ponds or storage reservoirs on the watershed.

**WATER SUPPLY OF NORTH EASTON VILLAGE DISTRICT, EASTON.**

*Chemical Examination of Water from the Well of the North Easton Village District.*

No organisms.

**WATER SUPPLY OF EVERETT.**

(See *Boston, Mystic Works.*)

**WATER SUPPLY OF FAIRHAVEN. — FAIRHAVEN WATER COMPANY.**

The advice of the State Board of Health to the Fairhaven Water Company with reference to the introduction of a water supply from tubular wells in the vicinity of the Nasketucket River will be found on page seventeen of this volume. Analyses of samples of water collected from wells near the river and from the river are given below.

## FAIRHAVEN.

The results found by analysis are somewhat remarkable, as they show that water from flowing wells only a short distance apart differed very much in quality, some of the water having its origin in a polluted source, and some of it being the natural water of the region. This subject is referred to quite fully in the advice of the Board. It is also worthy of note that there was a difference in the temperature of the water from wells driven to the same depth, that from the southerly well having a temperature, April 12, 1893, of 46.5 degrees, from the northerly well, 43 degrees, and from the middle wells, 48 degrees. The temperature of the water in the river at the same time was 55 degrees.

The works for taking water from this source were nearly completed at the end of 1893.

Odor, none. On heating, the odor of the first sample became faintly vegetable. — The wells are located in the vicinity of the river, about half a mile above the point where it is crossed by the Fairhaven branch of the N. Y., N. H. & H. R R. The first sample was collected from one of the middle wells in a line of six in the valley of the Nasketucket River; the second sample from the most northerly and the last from the most southerly well in this line.

Iron, .0030. Odor, faintly vegetable. — The sample was collected from the river at the dam of a small ice pond, located a short distance above the test wells.

*Microscopical Examination.*

Diatomaceæ, *Melosira*, 3; *Meridion*, 11; *Navicula*, 5; *Nitzschia*, 1; *Pinnularia*, 1; *Synedra*, 34; *Tabellaria*, 44. Miscellaneous, *Zoëglæa*, 6. Total, 105.

### WATER SUPPLY OF FALMOUTH HEIGHTS. — FALMOUTH HEIGHTS WATER COMPANY.

This village is a summer resort on Vineyard Sound in the southerly part of the town of Falmouth. The source of supply is a well about ten feet in diameter and twenty feet in depth, located a short distance north-west of the village. Water is pumped from the well to an elevated wooden tank upon Observatory Hill in the village, and is thence distributed to consumers through cast-iron mains. The reply of the State Board of Health to the Falmouth Heights Water Company, with reference to the use of this well as a source of water supply for the village of Falmouth Heights, may be found on page 18 of this volume.

\* June to December.

NOTE to analyses of 1893: Iron, .0181. Odor of the first sample, distinctly unpleasant, becoming disagreeable on standing; of the other samples, faintly vegetable. — The samples were collected from the reservoir near the gate-house, one foot beneath the surface.

The heights of water in this reservoir on dates when samples of water were collected for analysis were as follows: July 19, thirty-seven feet; October 16, eighteen feet; December 18, twenty-nine feet. High-water mark is forty feet.

Iron, .0407. Odor of the first sample, musty and disagreeable, becoming offensive on heating; of the second sample, none, becoming faintly vegetable on heating. — The samples were collected from the end of the pipe below the gate-house, and represent water drawn from the bottom of the reservoir. This reservoir is not used as a source of water supply, although it is owned by the city and is within the territory from which it is authorized to take water.

**WATER SUPPLY OF COHASSET. — COHASSET WATER COMPANY.**

The advice of the State Board of Health to the Cohasset Water Company relative to increasing its water supply may be found on page 17 of this volume. Analyses of water from present sources of supply and of samples collected during the investigations for an additional water supply are given on succeeding pages.

## FRAMINGHAM.

*Chemical Examination of Water from a Faucet in South Framingham, supplied from the Works of the Framingham Water Company.*

Odor of No. 10799, like tar; of the others, none. — The samples were collected from a faucet at the works of the Gosamer Rubber Company, which are located near the end of the distributing system just south of the Boston and Albany Railroad about a mile west of South Framingham and a little over two miles from the pumping station by way of the pipe line.

## Microscopical Examination.

No. 10799, Miscellaneous, *Zoëglæa*, 1126.

No. 11170, Fungi, *Orenothrix*, 78. Miscellaneous, *Zoëglæa*, 6. Total, 84.

No. 11478, Diatomaceæ, *Melosira*, 3. Fungi, *Orenothrix*, 1. Infusoria, *Peridinium*, 1. Total, 5.

No organisms were found in the remaining samples.

*Chemical Examination of Water from the Underdrain beneath the Sewers at Framingham.*

\* October.

Note to analyses of 1893: Odor, generally faintly vegetable and mouldy. — The samples were collected from the underdrain at its outlet.

The analysis of 1899 was made before sewage was admitted to the sewers. Several of the analyses made in 1890 and all of those of subsequent years were made by the city of Boston.

\* Where more than one sample was collected in a month the mean analysis for that month has been used in making the average.

† June to December.

‡ January to May.

§ June, three samples.

|| March.

NOTE to analyses of 1893: Iron, .0054. Odor, generally faintly vegetable or none; in June the odor became disagreeable and oily on heating the water. — The first five samples were collected from a faucet at the pumping station while pumping. No. 10567 was collected directly from the lake. The remaining samples were collected from a faucet in the town.

GARDNER.

Iron, none. Odor, distinctly vegetable and disagreeable, becoming faintly vegetable on heating. — The sample was collected from the pond at its northerly end, near the shore.

Reference is made to the quality of this water in a reply of the State Board of Health to the town of Whitman with regard to taking a water supply for the town from this pond and from other sources in the vicinity, which may be found on page 67 of this volume

Iron, .0045. Odor of the first sample, very disagreeable, disappearing on heating; of the second sample, vegetable; of the last, very faintly vegetable, becoming stronger and grassy on heating. — The first and last samples were collected directly from Crystal Lake; the second sample, from a faucet in the city supplied from Crystal Lake.

*Microscopical Examination.*

The total number of organisms per cubic centimeter found in these samples was as follows: In February, 8; in June, 311; in October, 56.

Iron, .0043. Odor of the first sample, none, becoming vegetable on standing; of the second sample, decidedly vegetable; of the third sample, faintly vegetable; of the remaining samples, none. — Sample No. 10760 was collected from the pump well at the pumping station; the remaining samples from the pond near the surface.

Odor, none. On heating, Nos. 14527 and 15453 had a faintly vegetable odor. — The samples were collected from a faucet at the pumping station.

*Microscopical Examination.*

No. 13878. Fungi, *Oreothrix*, 1. Miscellaneous, *Zoëglæa*, 10. Total, 11.

No. 13443. Fungi, *Oreothrix*, 5; *Molds*, 14. Miscellaneous, *Zoëglæa*, 2. Total, 21.

In the other samples no organisms were found.

## WATER SUPPLY OF FALL RIVER.

*Chemical Examination of Water from North Watuppa Lake.*

Odor, vegetable. — The first sample was collected from a faucet in the city, the second from a faucet at the pumping station, and the last from the gate-house at the lake.

*Microscopical Examination.*

The total number of organisms per cubic centimeter found in each of these samples was as follows: No. 13879, 600; No. 14202, 229; No. 14346, 228.

## HOLYOKE.

## WATER SUPPLY OF HOLYOKE.

The advice of the State Board of Health to the city of Holyoke, with regard to an additional water supply, may be found on page 19 of this volume. On pages 168 and 169 will be found analyses of samples of water collected from various sources examined in connection with the investigation for this supply.

*Chemical Examination of Water from Whiting Street Storage Reservoir,  
Holyoke.*

\* June to December.

; January to May.

1 December.

NOTE to analyses of 1893: Iron, .0101. Odor of the first three samples, distinctly vegetable, and of the first, also disagreeable; of the last three samples, faintly vegetable or none. On heating, the odor of all samples was distinctly vegetable. — The samples were collected from the reservoir.

## WATER SUPPLY OF HUDSON.

In the early part of 1893, particularly in January and the first part of February, this supply was affected by the presence of the organism *Uroglena*, the most noticeable characteristic of which is the oily odor which it imparts to water even when present in comparatively small numbers. This organism was present in the water supplies of Norwood and Plymouth in the years 1892 and 1893, and it has been found in other water supplies in the State. A description of this organism and an account of its effect upon the taste and odor

## HUDSON.

of water may be found in the twenty-third annual report of the State Board of Health, for 1891, pages 645-658.

*Chemical Examination of Water from Gates Pond, Berlin.*

\* Where more than one sample was collected in a month, the mean analysis for that month has been used in making the average.

† June to December.

Note to analyses of 1893: Iron, .0040. Odor, generally vegetable or none. A faintly oily odor was detected in Nos. 9875, 9916 and 10422. On heating, a decided oily odor was developed in the samples collected between January 13 and February 8 inclusive, and in the samples collected on May 22 and in June. — The samples were collected from the pond at the surface.

**GLOUCESTER.****WATER SUPPLY OF GLOUCESTER.**

The works of the Gloucester Water Company were taken by the city Oct. 1, 1895.

The advice of the State Board of Health to the city of Gloucester, relative to its present and prospective sources of water supply, may be found on pages 20-23 of this volume. Analyses of samples of water collected during the investigation of the present supply and of the proposed sources of supply are given in the following tables.

WATER SUPPLY OF HULL.

(See *Hingham*.)

WATER SUPPLY OF HYDE PARK AND MILTON.—HYDE PARK WATER COMPANY.

The works of this company for obtaining a supply of ground water in the vicinity of the Neponset River were enlarged early in 1893, by sinking thirty-three tubular wells, located between the old systems of tubular wells and the starch factory well mentioned in the annual

**HYDE PARK AND MILTON.**

report of the Board for 1892. The new wells are in parallel lines on either side of a suction pipe placed approximately at right angles to the river, their distances from the river varying from sixty-four to nearly two hundred feet. The new wells are two and a half inches in diameter and of various depths, ranging from about twenty to twenty-eight feet. Twelve of the wells nearest the river have been disconnected, but the remaining wells have been in use since they were connected with the pump in the summer.

The advice of the State Board of Health to the Hyde Park Water Company, with reference to the use of water from these wells, may be found on page 20 of this volume, and analyses of water from three are given on page 176. The temperatures of the water in the wells from which these samples were collected differed considerably one from another, and were as follows: of the well nearest the river (No. 5), forty-nine degrees; of the well near the middle of the group (No. 14), forty-one degrees; of the well farthest from the river (No. 36), forty-four degrees.

\* June to December.

† August and September.

‡ July.

NOTE to analyses of 1893: Iron, .0304. Odor, generally decidedly vegetable and musty, sometimes disagreeable or offensive. On heating, the odors are generally stronger and more frequently disagreeable or offensive. — The samples were collected from the river opposite the works of the Hyde Park Water Company. The river is not used as a source of water supply.

No. 11226, iron, .0300; No. 11225, iron, .0150. Odor of the first sample, none, becoming faintly vegetable on heating; of the last sample, distinctly vegetable. — The first sample was collected from Dow's Brook at a point a short distance above its mouth; the last sample, from Egypt River or Bull Brook, a short distance above the mouth of Dow's Brook. The samples were collected during an investigation for a water supply for Ipswich.

*Microscopical Examination.*

No. 11226. Diatomaceæ, *Synedra*, 1. Fungi, *Crenothrix*, 88. Miscellaneous, *Zoëglæa*, 12. Total, 51.

No. 11225. Diatomaceæ, *Asterionella*, 1; *Tabellaria*, 2. Fungi, *Crenothrix*, 46. Miscellaneous, *Zoëglæa*, 1. Total, 50.

## WATER SUPPLY OF KINGSTON.

The advice of the State Board of Health to the town of Kingston, with reference to taking an additional supply of water for the town from Jones River, may be found on page 21 of this volume.

## LAKEVILLE.

*Chemical Examination of Water from Long Pond, Lakeville.*

Iron, .0050. Odor of Nos. 10708 and 10948, vegetable; of the remaining samples, none. — The samples were collected from the pond five feet beneath the surface, in connection with an investigation for an additional water supply for New Bedford.

*Microscopical Examination.*

The number of organisms per cubic centimeter found in these samples varied from eighty in the first to three in the last, and averaged forty-eight.

Odor, faintly vegetable. — The sample was collected from the brook at the first road crossing above its junction with Broad Brook, and a short distance below the site of a proposed reservoir.

*Microscopical Examination.*

Diatomaceæ, *Cocconeis*, 1. Algae, *Protococcus*, 1. Total, 2.

**WATER SUPPLY OF HAVERHILL.**

In 1895 an additional supply of water was introduced into the city of Haverhill from East Meadow River in the north-easterly part of the city, and a storage reservoir was constructed upon the stream at Millvale, about half a mile from the point where it enters the Merrimack River.

The reservoir has an area of about 50 acres and a capacity of about 125,000,000 gallons. Its maximum depth at high water is 15 feet and its average depth 7 feet. It was thoroughly prepared for the storage of water by removing the soil, mud and vegetable matter from the area to be flowed.

The water from this source is pumped into the easterly end of Kenoza Lake through a 24-inch main about one mile in length, the surface of Kenoza Lake at high water being 18 feet above the high-water level of the Millvale Reservoir.

The watershed of East Meadow River tributary to the Millvale Reservoir has an area of 7.75 square miles, on which there is a very small population. There is one small pond on the watershed about 3 miles above the reservoir, and there is a considerable area of swamp in the vicinity of the river, a large portion being located within a short distance of the reservoir.

## LAWRENCE.

## WATER SUPPLY OF LAWRENCE.

As already stated in a previous portion of this report (page 3), a filter having an area of two and a half acres was constructed by the city of Lawrence during the past year, at a cost of about sixty-five thousand dollars, and since its completion in September the water supplied to the city has been filtered.

The reply of the Board to an application from the city of Lawrence for information as to the results of the filtration of its water supply, after the filter had been in use a little more than two months, may be found on page 22 of this volume.

A more complete description of the filter with a statement of the results obtained by its use will be found in a subsequent portion of this report, also additional analyses of the Lawrence water made at the Lawrence Experiment Station.

*Chemical Examination of Water from the Merrimack River above Lawrence, opposite the Intake of the Lawrence Water Works.*

Iron, .0139. Odor, vegetable and musty.—The samples were collected from the river opposite the intake of the Lawrence Water Works, about one foot beneath the surface. For a record of the quantity of water flowing in the river on dates when samples of water were collected for analysis, see page 186. For a summary of the analyses of previous years, see "Merrimack River" in the chapter on "Examination of Rivers."

**LAWRENCE.**

*Microscopical Examination of Water from the Merrimack River above Lawrence, opposite the Intake of the Lawrence Water Works.*

\* This sample was collected on the day when the new filter was first operated, and represents the first water that passed through; it is abnormal on this account, and is therefore omitted from the average.  
† June to December.

NOTE to analyses of 1893: Iron, .0156. Odor, vegetable and musty, occasionally none. — The samples were collected from a faucet in the check-valve just beyond the pump, and, until September, 1893, represent a mixture of water from the river and the filter-gallery, though but a small portion of the water came from the latter source. Beginning with September, the samples represent water from the river after passing through the new filter. The odor of the filtered water was vegetable but never musty.

\* June to December.

NOTE to analyses of 1893; Iron, .0117. Odor, generally distinctly vegetable, frequently mouldy. — The samples were collected from a faucet at the gate-house and represent water flowing out of the reservoir. After September 20, the reservoir was supplied with filtered water, and the mouldy odor was not noticed after that date.

**LAWRENCE.***Microscopical Examination of Water from the Distributing Reservoir of the Lawrence Water Works.*

Odor, of No. 10275, faintly musty, becoming stronger on heating; of No. 11527, faintly vegetable; of the remaining samples, none. — The first two samples were collected from a faucet supplied through 1,800 feet of two-inch wrought-iron pipe, leading from the end of a six-inch main; the remaining samples, from faucets in the village.

\* June to December.

NOTE to analyses of 1893; Iron, .0133. Odor, generally distinctly vegetable, sometimes also unpleasant; on heating the odor is stronger, and in the first and last samples also disagreeable.—— The samples were collected from the reservoir near the gate-house at a depth of about one foot beneath the surface.

Ever since the examinations of the water of this reservoir were begun, in 1887, it has contained an abundant growth of organisms in the summer and autumn, which are the cause of the high albuminoid ammonia shown in the tables of analyses. The reservoir was formed by flooding 58 acres of land, a portion of it swamp, to a maximum depth of 12 feet, without removing the stumps of trees or the soil; and it is of interest to note that although the reservoir has been flooded for twenty years, the water has not shown any improvement in quality within the time covered by the examinations.

Iron, .0129. Odor, generally distinctly vegetable, becoming fainter on heating. — The samples were collected from the reservoir.

This reservoir was enlarged in 1891 by the construction of a new and higher dam, increasing its depth to 23 feet and its capacity from 7,000,000 to 40,000,000 gallons. It is said that all loam and vegetable matter was removed from the land flowed by raising the dam.

Iron, .0133. Odor generally distinctly mouldy or musty, and frequently also vegetable. — The samples were collected from the river about one foot beneath the surface.

For a summary of analyses of previous years see "Merrimack River" in the chapter on Examination of Rivers, in a subsequent portion of this report.

*Microscopical Examination of Water from the Merrimack River above Lowell, opposite the Intake of the Lowell Water Works.*

\* June to December.

† August and September.

‡ July.

NOTE to analyses of 1895: Odor, generally decidedly vegetable and musty or disagreeable, and occasionally offensive.—The samples were collected from the river, opposite the works of the Hyde Park Water Company. The river is not used directly as a source of water supply.

\* Where more than one sample was collected in a month the mean analysis for that month has been used in making the average given at the bottom of the table.

NOTE to analyses of 1893; Iron, .0234. Odor, distinctly vegetable and generally also unpleasant; on heating, the odor is somewhat stronger. — The samples were collected from, the pond near the gate-house, one foot beneath the surface.

Odor, none. — The samples were collected from a spring, located very near Dow's Brook, about 500 feet above the upper end of the Dow's Brook storage reservoir.

*Microscopical Examination.*

No. 14371. Diatomaceæ, *Meridion*, 6.

No. 14726. No organisms.

## WATER SUPPLY OF KINGSTON.

The advice of the State Board of Health to the town of Kingston with reference to the use of lead pipes in the distribution of the water supplied to the town may be found on pages 30 to 32 of this volume.

*Chemical Examination of Water from a Faucet supplied from the Kingston Water Works.*

Fungi, *Crenothrix*, 3.

## WATER SUPPLY OF LAWRENCE.

The following tables contain analyses of the unfiltered Merrimack River water, and of the filtered water at the pumping station and at the distributing reservoir. The results of more extended chemical and biological examinations of the water before and after filtration through the sand filter may be found in a subsequent portion of this report.

## LYNN.

\* The water in these ponds is sometimes raised somewhat above ordinary high water in the latter part of the spring in order to increase the storage.

## WATER SUPPLY OF MALDEN, MEDFORD AND MELROSE.

On Feb. 9, 1893, when Spot Pond had reached a much lower level than ever before, the State Board of Health addressed a communication to the Water Boards of Malden, Medford and Melrose, urging the necessity of taking immediate measures for increasing the amount of water in the pond, and giving estimates of the probable condition of the pond on Jan. 1, 1894, under minimum, average and maximum conditions of rainfall during the remaining eleven months of the year.

The estimates of the amount of water which would enter the pond were based upon the yield per square mile of watershed, as deduced from measurements of the flow from the Sudbury River watershed during the past eighteen years, and the influence of the evaporation from the surface of the pond was also included. The draft from the pond was reckoned at 600,000 gallons per day for each community, which was about the rate at which water was being drawn from the pond a few months before. It was urged, however, in the communication, that this draft from the pond

**MALDEN, MEDFORD AND MELROSE.**

should be reduced by taking as much water as possible from supplementary sources.

It is gratifying to note that at the end of the year the quantity drawn from the pond was 119,000,000 gallons (equivalent to a depth of about 2.5 feet on the pond) less than it would have been if each of the three communities had continued to draw at the rate of 600,000 gallons per day; the diminished draft being due in part to a restriction of use and waste, but still more to the amount of water supplied from supplementary sources throughout the whole year at Malden, and during the latter part of the year at Medford and Melrose.

The yield of the Sudbury River watershed during the eleven months from Feb. 1, 1893, to the end of the year was very nearly the same as the average for those months during the preceding eighteen years, and with average conditions the prediction contained in the communication indicated that the quantity of water in the pond would be increased 46,000,000 gallons on Jan. 1, 1894, upon the assumption that 600,000 gallons per day would be drawn by each community. To this quantity should be added the 119,000,000 gallons due to the smaller draft from the pond, making 165,000,000 gallons as the increased amount that should be in the pond on this date, according to the prediction.

By consulting the records of the height of the pond, it was found that it contained 184,000,000 gallons more on Jan. 1, 1894, than on Feb. 1, 1893, which showed a difference between the predicted yield in an average year and the actual yield of only 19,000,000 gallons; by taking into account the slight variation in the yield of the Sudbury River during these eleven months from the yield during the same months in an average year a still closer agreement was found. This is a further confirmation of what has already been well established, namely, that the capacity of this source may properly be reckoned upon the basis of the size of its watershed, assuming that the flow from each square mile is the same as from the watershed of Sudbury River.

\* May to December.

NOTE to analyses of 1893; Iron, .0260. Odor, faintly vegetable and occasionally unpleasant; on heating, the odor is generally stronger; in July it was oily, in August and September, fishy, and in other months frequently grassy or mouldy. The samples were collected either from a faucet in the pumping station of the Malden Water Works or from the pond near by.

The averages of analyses for the years 1892 and 1893 when compared with the averages of previous years indicate a change in the character of the water, which is doubtless due to the fact that during these two years the surface of the water in the pond remained very much below high water mark.

\* Three samples in November and December.

† June and October.

NOTE to analyses of 1893; Odor, none. — The samples were collected from a faucet at the pumping station, while pumping, with the exception of No. 10612, which was collected from a drinking fountain.

## MARBLEHEAD.

## WATER SUPPLY OF MARBLEHEAD.

The works from which the water supply of Marblehead is drawn were enlarged in 1892 by the addition of a group of five tubular wells situated about 800 feet south-east of the pumping station. The depth of the wells varies from 25 to 53 feet. From April until November, 1893, water from these wells was pumped, by means of an auxiliary pump, into the large collecting well near the pumping station. In 1893 a further addition to the works for obtaining a supply of ground water was made by the construction of a small collecting well about eight feet in depth, near a small pond, and a short distance from the tubular wells just described. This well was completed about Nov. 1, 1893, and has been connected with the large collecting well by a siphon.

The driven-well system in the marsh near Loring Avenue has been reconstructed, and during 1893 water has been drawn, when necessary, from 39 tubular wells in this vicinity. The water of these wells is affected by their proximity to the sea, and the large amount of chlorine present at times in the water supplied to the town is due chiefly to the use of water from this source.

The large collecting well constructed in 1890 continues to be the chief source of supply, and at times furnishes all of the water used by the town.

Odor, none. — The samples were collected either directly from the well or from a faucet at the pumping station while pumping from the well.

All of the waters in this and the two following tables contain iron in considerable amount, which oxidizes on exposure to the air, making the water somewhat turbid and colored.

Odor, none; occasionally an earthy odor is developed on heating. — The samples were collected from a faucet in the town, and represent a mixture of water drawn from the various sources of supply.

*Microscopical Examination.*

A very few *Zoëglæa* were found in March, April and May. In the remaining months the water contained no organisms.

## WATER SUPPLY OF MARLBOROUGH.

At the beginning of 1893, the new works to furnish an additional supply of water for the city of Marlborough from Millham Brook were nearly completed, and they were finished in season to permit the pumping of 38,000,000 gallons of water (nearly a quarter of the total amount consumed by the city in 1892) during the spring, when the flow in the brook was large. Of this amount 20,000,000 gallons were pumped directly into the distributing reservoir and the remainder into Lake Williams, which, at the beginning of the year, was at a much lower level than ever before. During the month of April the city was supplied wholly with water from Millham Brook.

The additional water works at present consist of a very small reservoir on Millham Brook, a pumping station near the reservoir, and a force main from which water can be discharged either into Lake Williams or, by means of a connection with the original force main, into the distributing reservoir.

Iron, .0033. Odor of the first sample, faintly earthy; of the second, distinctly vegetable and unpleasant; of the remaining samples, none. On heating, a faintly vegetable odor was noticeable in the second and third samples. — The first sample was collected from a faucet in the town, the remaining samples directly from the pond. The difference between the analysis of the sample collected in the village and those from the pond indicates that a large amount of ground water finds its way into the pipe leading from the pond to the pumping station.

Odor, none, becoming very faintly vegetable on heating. — The sample was collected from a spring near Vine Brook about a third of a mile above North Street. This spring is used as a source of water supply by a large straw factory, and by a portion of the village of Medfield.

*Microscopical Examination.*Diatomææ, *Synedra*, 1.

## WATER SUPPLY OF MEDFIELD INSANE ASYLUM.

*Description of Works.* — This asylum is a State institution which had not been occupied up to the end of 1893. The water works were completed in September, 1893. The supply is obtained from a system of 20 two and one-half inch tubular wells, located on

## LOWELL.

exposure to the air, giving the water at first a milky turbidity, and subsequently precipitating in the form of a rusty sediment.

*Chemical Examination of Water from the Merrimack River above Lowell, opposite the Intake of the Lowell Water Works.*

\* June to December.

† January to May.

‡ September to December.

NOTE to analyses of 1895: Odor, generally vegetable and musty or mouldy, sometimes unpleasant or disagreeable. — The samples were collected from the river, about 1 foot beneath the surface.

For a comparison of the analyses of the river at Lowell and Lawrence for a series of years, see "Merrimack River" in the chapter on "Examination of Rivers" in a subsequent portion of this report.

## MEDFORD.

two feet. These are approximately in two parallel lines and the extreme wells are about three hundred feet apart in an easterly and westerly direction, and one hundred and sixty feet in a northerly and southerly direction. As these wells did not furnish as much water as was desirable, in view of the low level of the water in Spot Pond, additional works were constructed early in 1894 for pumping water from the unpolluted upper portion of the brook.

Analyses of water from various sources within the town are given below. Further information regarding the water supply of Medford from Spot Pond may be found on pages 29-32 and 203, and analyses of water from the pond may be found on page 205.

*Chemical Examination of Water from Tubular Wells used as an Additional Source of Water Supply for Medford.*

Iron, .0100. Odor, very faintly vegetable. — The sample was collected from the brook near the corner of Elm and Forest streets, Medford. Early in 1894 the town began pumping water from the brook at this point.

*Microscopical Examination.*

Diatomaceæ, *Meridion*, 1; *Naricula*, 1; *Nitzschia*, 1. Miscellaneous, Zoöglæa, 11. Total, 14.

**WATER SUPPLY OF MELROSE.**

Several communications of the State Board of Health to the town of Melrose, with reference to taking an additional water supply for the town from sources in North Andover, and from various sources within the town of Melrose, may be found on pages 34-40 of this volume.

**MELROSE.**

In August, 1893, an additional supply of water was introduced from a system of tubular wells, owned by a private company, and located in the westerly part of the town, near the boundary line between Melrose and Stoneham. The works consist of a system of fifteen two and one-half inch tubular wells varying in depth from thirty-five to forty-five feet, all located in the vicinity of Spot Pond Brook, north of Wyoming Avenue. The wells are connected with a temporary pump, and water is pumped directly into the main pipe in Wyoming Avenue, which conveys water from Spot Pond to the town.

Analyses of water from this source and from other sources within the town are given in the tables below. Further information regarding the water supply of Melrose from Spot Pond may be found on pages 29-32 and 203, and analyses of water from the pond on page 205.

*Chemical Examination of Water from Tubular Wells in the Valley of Spot Pond Brook, near Wyoming Avenue, used as an Additional Source of Water Supply for Melrose.*

Odor, none. — The first two samples were collected from the discharge pipe of the pump drawing water from the tubular wells; the remaining samples from a faucet at the temporary pumping station while pumping.

*Microscopical Examination.*

A few *Zoëglæ* were found in the samples collected in the latter part of September and in October and November. In the remaining samples no organisms were found.

Odor, none. — The first three samples were collected during a pumping test from a group of five tubular wells about fifty feet distant from the northerly shore of Ell Pond. The first sample was collected soon after beginning the test and the third sample at the end, after pumping fourteen and a half days at a rate of about 480,800 gallons per day. The last sample was collected from a small hand pump after pumping a few minutes from one of the wells. The average depth of these wells was 38 feet.

*Microscopical Examination.*

No. 10541. Fungi, *Spirocheta*, 2. No organisms were found in the remaining samples.

## MENDON.

## MENDON.

The advice of the State Board of Health to the town of Mendon, with reference to taking a water supply for the town from Mendon Pond, also known as Nipmuck Pond, may be found on pages 40-41 of this volume.

The advice of the Board to the town of Uxbridge with reference to the use of this pond as a source of water supply for that town is given in the annual report for 1892, pages 46-49. For analyses of samples of water collected from Mendon Pond, see Uxbridge.

## WATER SUPPLY OF METHUEN.

The advice of the State Board of Health to the town of Methuen with reference to obtaining a water supply for the town from the ground in the vicinity of Sargent's Brook, and, subsequently, with reference to obtaining a water supply from the ground in the vicinity of the Spicket River near the point where it is joined by the brook flowing from Harris Pond, may be found on pages 41-42 of this volume. Works for supplying the town with water from wells in the vicinity of the Spicket River were begun near the end of 1893.

*Chemical Examination of Water from the Spicket River at Mouth of Harris Pond Brook, and from a Tubular Well in the Vicinity.*

Odor of the first two samples, none; of the last, faint. — The first sample was collected from a brook in Sargent's Meadow, in the easterly part of Methuen. This brook is a tributary of Bear Meadow Brook. The last two samples were from tubular wells in Sargent's Meadow; the first from a single well and the last from a group of seven two and one-half inch tubular wells, collected from the discharge pipe of a pump after pumping continuously for eight hours.

## MILTON.

## WATER SUPPLY OF MILTON. — MILTON WATER COMPANY.

The water supplied by this company to the town is purchased from the Hyde Park Water Company. A statement in regard to the supply and analyses of the water may be found on pages 173-176. Analyses of samples of water from Pine Tree Brook, and from a test well near it, made in connection with an investigation for a new source of water supply for Milton, are given below.

*Chemical Examination of Water from Pine Tree Brook, Milton.*

\* Where more than one sample was collected in a month, the mean analysis for that month has been used in making the average.

† June to December.

‡ January to June.

NOTE to analyses of 1893; Iron, .0065. Odor of the first sample, strongly vegetable and unpleasant, becoming strongly oily on heating; of the second sample, none, becoming decidedly oily on heating; of the last sample, decidedly vegetable and unpleasant; of the remaining samples, generally faintly vegetable or none. — The first three samples were collected directly from the lake; the remaining samples from a faucet at the pumping station.

## WATER SUPPLY OF NAHANT.

(See *Swampscott.*)

## WATER SUPPLY OF NANTUCKET. — WANNACOMET WATER COMPANY.

Wannacomet Pond, the source of supply of this company, has given trouble on several occasions owing to the presence in the water of abundant growths of the organism *Anabæna*, which has generally appeared about midsummer and disappeared in October. The pond is a natural basin with sandy shores and a muddy bottom, having an area of about eight acres and a general depth of about fourteen feet. It has no visible inlet or outlet and is supplied with water which percolates into it from the sandy territory with which

## NANTUCKET.

the pond is surrounded. In 1891 the *Anabæna* gave more serious trouble than in any previous year, and in order to provide a remedy in the event of any recurrence of the trouble a filter was constructed near the shore of the pond for use at such times. In 1892 the pond was wholly free from these organisms, and there was no occasion to use the filter; but in 1893 the organisms reappeared in great numbers, and the filter was used nearly all of the time from August 8 to October 18.

A description of the filter and an account of the results obtained by its use during the period above indicated are contained in a paper read by Mr. W. F. Codd, superintendent of the works, before the New England Water Works Association, and many of the following statements are taken from this paper. The subject is a particularly interesting one because it is the first attempt to filter in this manner a water containing large numbers of algæ.

In constructing the filter a water-tight circular basin or reservoir, sixty-four feet in diameter at the bottom and six feet deep, with slopes of two horizontal to one vertical, was first made. The bottom of this basin consisted of a layer of puddle, one foot in thickness, and the slopes were formed of the same material. In the centre a circular brick well was built to collect the filtered water, 15.25 feet in diameter inside and eight feet deep. The bottom of this well is of concrete and is somewhat lower than the bottom of the filter. The construction of the filter proper was then begun by covering the clay bottom with a layer of sand one inch in thickness, over which was placed a layer of round and broken stones about two feet in thickness. Imbedded in the layer of stones are four main lines of twelve-inch vitrified pipe, each having six branches extending out from each side, designed to collect the filtered water and convey it to the collecting well. Above the layer of stones is a six-inch layer of gravel, and then a layer of filtering sand from twelve to sixteen inches in thickness, which was placed in three layers, each rolled with a stone-roller. Wrought-iron aeration pipes, perforated with holes, three thirty-seconds of an inch in diameter and two feet apart, were laid in the bottom of the collecting well and inside of every vitrified pipe under the filter bed, it being the intention to aerate not only the filtered water but the filter bed itself.

## NANTUCKET.

The surface of the filter is level and about five feet above high-water mark in the pond, so that water has to be pumped upon it. The pond water is pumped through a six-inch pipe which rises vertically through the filtering material to the surface of the filter, and the water is kept at a depth of from twelve to eighteen inches above the surface of the sand. The filter was kept saturated and covered with water at all times, although, as it was the custom to pump water upon the filter and draw the filtered water from the collecting well at the same time, the filtration through the sand took place only while the pumps were in operation. As a rule air was forced through the aeration pipes during most of the time when the pumping was in progress.

The rate of consumption during the summer ranged from 150,000 to 220,000 gallons per day, so that the rate of filtration if it had been continued through the whole twenty-four hours would have been from 1,420,000 to 2,080,000 gallons per acre per day (1.4 to 2.0 gallons per square foot per hour). The pumps were generally operated from an hour to an hour and a half at a time, while the tank was being filled, and then shut down for three or four hours. Under these circumstances the filtration took place at a much more rapid rate than is above indicated. It is stated that the filter is intended to operate at the rate of five gallons per square foot per hour.

As already indicated, the *Anabæna* appeared in such numbers in 1893 as to cause complaint from the water consumers, and the operation of the filter was begun on August 8. At first the results appeared to be satisfactory, 98 per cent. of the organisms being removed from the water on August 14, and nearly all of the odor and color. After twelve days' use, while the filtered water still appeared to be clear, complaints of the odor of the water began to be made by the consumers. Two days later it was noticed that a scum had formed upon the surface of the sand and the filter had become clogged. This clogging was relieved by raking the surface, and did not occur again. After twenty-two days' use the odor of the filtered water was so strong that the use of the filter was discontinued, the water was drawn down and a layer half an inch in depth was removed from the surface of the filter. The greater part of the matter removed from the water by filtration was found within a

## NANTUCKET.

quarter of an inch of the surface. In some places, however, the sand was stained to a depth of eight or ten inches. It was also noticed that the air used in aerating the filter had passed up through the material unevenly and had come to the surface at several places where little craters were formed. The portion of the aerating pipes extending beneath the filter bed were accordingly disconnected and were not used again during the season. The filter was again used for a few days beginning September 1, but the odor of the filtered water was so strong that it was again discontinued. Up to this time light was admitted to the collecting well, but afterward it was excluded.

It is also to be noted that these unfavorable results were obtained during the portion of the year when the pond water had a high temperature, which was increased by the exposure of the water in a thin layer upon the filter bed and by the warm air pumped in for aeration from the engine-room. After September 29, when the temperature of the water was below sixty degrees Fahrenheit, the filter was operated without any trouble and there was said to be no odor. On October 18 the filtration was discontinued for the season, as the *Anabæna* had disappeared from the pond.

The results of the chemical and microscopical examinations as given in the following tables show that a very large proportion of the *Anabæna* were at all times removed by filtration, but at times there was a very abundant development of *Zoöglæa* in the filtered water. For instance, in the sample collected on September 20, when the unfiltered water contained 508 *Anabæna* and *Anabæna* spores per cubic centimeter, the number in the filtered water was 63. In the unfiltered water there were no *Zoöglæa* and in the filtered water 480. On this date the amount of organic matter as indicated by the albuminoid ammonia was reduced only about one-fourth, but as a rule nearly three-fifths of the organic matter was removed by filtration.

## NANTUCKET.

*Comparison of Examinations of Water from the Wannacomel Water Company's Works before and after Filtration.*

[NOTE.— Figures in bold-faced type show the results of examinations of water from the pond. Figures in Roman type show results of examinations of the water after passing through the filter.]

Odor, generally distinctly vegetable and unpleasant or disagreeable. — Nos. 10923 and 10983 were collected directly from the filter; the remaining samples, from a faucet at the pumping station while drawing water from the filter.

Odor, none. — Nos. 10435 and 11503 were collected from faucets in the village; the remaining samples either directly from the well or from a faucet at the pumping station while pumping.

*Microscopical Examination.*

An insignificant number of organisms was found in all but one of these samples.

## NEW BEDFORD.

\* Exclusive of No. 10896.

† June to December.

NOTE to Analyses of 1893; Iron, .0223. Odor, vegetable and grassy or sweetish. — The samples were collected from the conduit at its entrance to the receiving reservoir. Water from Little Quittacas Pond was drawn into the storage reservoir from July 23 to about Oct. 1, 1893.

## NEWBURYPORT.

## WATER SUPPLY OF NEWBURYPORT.—NEWBURYPORT WATER COMPANY.

The use of water from the Merrimack River by the Newburyport Water Company for the supply of the city was the subject of a communication from the State Board of Health\* to the company in November, 1892, pointing out the danger of infection from typhoid fever incurred by the use of this source and advising that a further supply of pure water be obtained without delay. The continued use of the river water was the apparent cause of an epidemic of typhoid fever in Newburyport in January and February, 1893, which led the Board to send a letter relative to this subject to the mayor of the city early in March, a copy of which may be found on page 43 of this volume. The city of Newburyport subsequently applied to the State Board of Health for advice relative to the use of water from the Artichoke River, either directly or after filtration, for the supply of the city, and the reply of the Board may be found on page 44.

The Newburyport Water Company increased its ground-water supply in 1893 by taking the Jackman Spring, so called, and providing a temporary pump and pipe to pump and convey the water from this spring to the present works. It also constructed a well about fifty feet in diameter and fourteen or more feet in depth, a short distance from its present wells, and near the edge of the small reservoir by the pumping station. The works as enlarged, however, are not likely to furnish a sufficient supply for the city of Newburyport.

It will be noticed by reference to the table of analyses on page 242 that a very unusual amount of chlorine was at times present in the water supplied by the company to the city. This result is due to the use of water from the Merrimack River which contained a small amount of sea water.

Analyses of water from the Artichoke River, and from other sources, examined in connection with the investigation of new sources of water supply by the city, will be found in tables which follow.

---

Odor, none. — The first sample was collected from a tubular test well just below Frost's ice pond in the valley of a tributary of Little River, about one mile south-west of the centre of the city of Newburyport; the second sample from a tubular test well located on the northerly side of Little River just below the point where it is crossed by the Byfield road, about on the line between Newburyport and Newbury; the last sample, from a tubular test well in the valley of Little River, about half a mile or more north-west of the well last described.

Iron, of the first sample, .0055; of the second, .0120; of the last two, .0110. Odor of the first two samples, faintly vegetable; of the last two, distinctly vegetable. — The first two samples were collected from the Artichoke River, about two miles above its mouth, at the Quaker Church Road crossing; the last two samples from the west branch of the Artichoke River at the first road crossing above its junction with the main stream.

*Microscopical Examination.*

The total number of organisms found in each of these samples was as follows: — No. 10265, 42; No. 11467, 3; No. 11389, 12; No. 11468, 8.

\* June to December.

† February.

NOTE to analyses of 1893; Odor of 10149, very faintly vegetable; of the remaining samples, none. — The samples were collected from a faucet at the pumping station, and represent the water as it comes from the covered filter-gallery.

Analyses for the years 1887 to 1890, inclusive, represent water drawn from an open filter-basin. In 1890 the works for collecting ground water were enlarged by the construction of a long wooden filter-gallery, reinforced by tubular wells. A portion of this gallery, seven hundred and thirty-two feet in length, replaced an equal portion of the old open filter basin. In 1892 the remaining portion of the open filter-basin was replaced by an extension of the filter-gallery, and after December of that year the water pumped for the supply of the city was not exposed to light at any point.

## NORTH ANDOVER.

The advice of the State Board of Health to the town of North Andover with reference to taking a supply of water for the town from Great Pond may be found on page 44 of this volume. The following analysis of a sample of water from Boston Brook in North Andover was made during an investigation for a new source of water supply for Melrose.

*Chemical Examination of Water from Boston Brook, North Andover.*

## WATER SUPPLY OF NORTH BROOKFIELD.

*Description of Works.*—The works are owned by the town and were completed in 1893. The sources of supply are Doane Pond and North Pond, formerly known as Horse Pond, supplemented by water diverted into it from North Brook. Water is pumped by water power at a station near Doane Pond to a distributing reservoir on Bell Hill and thence distributed to the town.

Water can be drawn from either pond, but it is proposed to draw the supply for domestic use from Doane Pond, using the surplus water from Doane Pond, in connection with the water from North Pond, to furnish power for pumping.

## NORTH BROOKFIELD.

The areas of watersheds (including the water surfaces) of sources controlled by the town, as determined by actual survey, are as follows :

|                                             |                  |
|---------------------------------------------|------------------|
| North Brook, . . . . .                      | 487.9 acres.     |
| Side Hill Canal from North Brook, . . . . . | 25.0 "           |
| North Pond, . . . . .                       | 195.6 "          |
| Doane Pond, . . . . .                       | 899.7 "          |
| Total, . . . . .                            | <u>1,608.2</u> " |

The size of the Doane Pond watershed, as given in the table, includes the whole of Stoddard Brook, which has a watershed of 425.8 acres. Provision has been made by which the water of nearly all of this brook can be turned into North Pond when it is desirable to do so.

With the exception of a portion of the watershed of North Brook, which rises in New Braintree, the watersheds of the sources of supply are within the limits of North Brookfield.

North Pond has an area of 69.6 acres and a capacity of about 350,000,000 gallons. It has been used for many years as a storage reservoir to supply power to a mill situated just below Doane Pond. A new dam six feet higher than the old one has been constructed by the town about 500 feet down stream from the old dam, thus greatly increasing the area and storage capacity of the pond. It is said that the pond is thirty feet deep in some places and may average eighteen feet. The water of North Pond is conveyed to the pumping station, situated just below Doane Pond, by means of a canal, without passing through Doane Pond.

Doane Pond is an artificial reservoir constructed many years ago for use as a mill pond. Since its acquisition by the town as a source of water supply the dam has been raised three feet, increasing its area to 30.9 acres and its capacity to 53,800,000 gallons.

A filter entirely surrounded by water has been constructed at Doane Pond near the dam, by building two concentric walls having an annular space five feet wide, filled with gravel, between them. In the centre is a filtered-water well fifteen feet in diameter and fifteen feet deep. Water for the supply of the town is drawn from this well.

The distributing reservoir is rectangular in shape, 159 by 117 feet at the foot of the slopes and 222 by 180 feet at the top of the slopes

**NORTH BROOKFIELD.**

inside. It is nineteen feet in depth from the top of the embankments and when filled to a depth of fifteen feet will contain about 2,950,000 gallons of water. The slopes are lined with clay puddle four feet in thickness, covered with a six-inch layer of broken stone, upon which is laid a stone paving one foot in thickness. The bottom is covered with broken stone and binding material to a depth of six inches.

Water enters the reservoir at the bottom on the north side and is drawn out about one foot from the bottom on the south side. An arrangement has been made whereby water may be sprayed into the reservoir from a pipe near its centre. It is intended to pump all water to the distributing reservoir, but a direct connection has been made whereby water may be pumped directly to the town in case of emergency. The distributing mains are of cast-iron.

*Chemical Examination of Water from Faucets in North Brookfield, supplied from the North Brookfield Water Works.*

**WATER SUPPLY OF NORWOOD.**

The organism *Uroglæna*, which was present in large numbers in the water of Buckmaster Pond in 1892, reappeared in much smaller numbers for a short time in the early part of 1893, and also in very small numbers toward the end of the year. A description of this organism and an account of its effect upon the taste and odor of water may be found in the annual report of the State Board of Health for 1891, pages 645-658.

\* June to December.

NOTE to analyses of 1893: Iron, .0057. Odor of the first sample, faintly vegetable, becoming faintly oily on standing or on heating; of the second sample, faintly vegetable, becoming strongly oily on heating; of the third sample, none, becoming faintly oily on heating; of the remaining samples, generally faintly vegetable, frequently none, rarely mouldy or grassy. — The samples were collected from the pond generally from five to eleven feet beneath the surface.

## ORANGE.

factory than that from other portions of the works, and to use the surplus water not needed for the supply of the town to furnish power for pumping; but an auxiliary steam plant has been provided at the pumping station for use at times when the supply of water is insufficient to furnish the power needed.

Coolidge Brook is a small tributary of Miller's River from the south which joins the river at a point about one and one-half miles below the village of Orange. The collecting reservoir is located just above the point where the brook is crossed by the Holshire road, about one and three-quarters miles from its mouth. The drainage area of the brook at this point is estimated to be about 1.38 square miles. The reservoir covers an area of about 0.72 acre, and it is said to have a capacity of 2,045,000 gallons when filled to the crest of the overflow, which is three feet below the top of the dam. The loam and sub-soil are said to have been removed from all of the area flowed. The water which passes the overflow is conveyed through a 48-inch pipe two hundred and fifty feet in length and discharged into North Pond.

Provision has been made for filtering the water drawn from Coolidge Brook for the supply of the town, by constructing on the up-stream side of the dam a rectangular filter-chamber of rubble masonry, 10 feet long, 7.5 feet wide, and of a height equal to that of the dam. The filter, which is on the up-stream side, is 5 feet 6 inches in width and of the same height as the walls of the chamber; the filtering material, consisting of sand or gravel, is four feet in thickness, and is retained between perforated wooden planks lined with copper wire screens.

It is the intention to have the top of the chamber closed tightly in order that water may be run back through it under pressure so as to wash the filter. All matter forced out of the filter in this way will mingle with the water in the reservoir. A 10-inch waste pipe is laid beneath the dam to provide for emptying the reservoir when necessary, and to waste the dirty water at times when the filter is being cleaned.

North Pond is located at the head of the middle branch of the Swift River, and originally had an area of about sixty acres. The area and storage capacity of the pond have been greatly increased by the construction of two dams, raising the surface of the pond to

**ORANGE.**

a level ten feet above the former high-water mark. One of the dams is located at the natural outlet of the pond, and the other at the northerly end at a low place in the divide between the Swift and Miller's rivers, over which water would otherwise pass into Coolidge Brook.

The present area of the pond at high water is 132 acres, and the increase in its storage capacity, obtained by raising the level ten feet, is said to amount to 357,000,000 gallons. The drainage area of the pond, including water surfaces and exclusive of Coolidge Brook, is estimated to be 0.66 of a square mile. By increasing the height of the water in the pond, a considerable area of swamp land has been flooded, which was prepared for flowage only by the removal of the trees.

Water from North Pond is drawn through a canal, the bottom of which at its upper end is about 11.41 feet below high-water mark, to Coolidge Brook, and flows in the channel of the brook to the Greenhalge Reservoir, at a distance of a little less than a mile from the pond.

Greenhalge Reservoir covers an area of about 1.9 acres and is said to have a capacity of 1,058,000 gallons. It was originally a mill pond, and after its purchase by the town was enlarged by the construction of a new and higher dam.

The pumping station is located in the valley of the brook just below the Greenhalge Reservoir, and from this point water is pumped to a distributing reservoir situated on Walnut Hill, about a mile south-west of the village of Orange and between it and the pumping station.

The distributing reservoir has the form of a rectangle, except that one end is semi-circular; it is 162 feet 6 inches in length by 80 feet in width on the bottom, and 20 feet in depth from the top of the embankment. When filled to high-water mark, which is five feet below the level of the embankment, it contains 2,125,000 gallons. The slopes are lined with clay puddle four feet in thickness, covered with a six-inch layer of broken stone, upon which is laid a stone paving one foot in thickness. The bottom is also of puddle four feet in thickness, covered with a six-inch layer of broken stone. Water enters the reservoir through a pipe laid along its bottom, and is drawn out at the opposite end. Provision has been made

## ORANGE.

for shutting off the reservoir from the rest of the system and pumping water directly to the town if necessary. The distributing mains are of cast iron; service pipes are of galvanized iron.

## PLYMOUTH.

## WATER SUPPLY OF PLYMOUTH.

In the early part of 1893 the organism *Uroglena*, which was present in considerable numbers in 1892, made its appearance in the water of Little South Pond, and was very abundant in the first part of February. It had entirely disappeared by the end of March and is said not to have been noticed again during the remainder of the year. A description of this organism, and its effect upon the taste and odor of water, was given in the Twenty-third Annual Report of the State Board of Health, pages 645-658.

Iron, none. Odor of the first sample, distinctly oily, becoming decidedly oily on heating, and strongly oily after standing one day in the laboratory; of the last sample, none. — The samples were collected from the pond.

*Microscopical Examination.*

No. 9968. Infusoria, *Uroglena*, very abundant.

No. 10179. Miscellaneous, *Zoëglæa*, 4.

## WATER SUPPLY OF PROVINCETOWN.

Population in 1890, 4,624. The works are owned by the town, and were completed in 1893. The supply is taken from a system of six tubular wells located about three-fourths of a mile north of the centre of the village. The wells are five inches in diameter, average twenty-eight feet in depth, and are the same that were used during a pumping test made in 1892. The material in which the wells were sunk is loose sand, which, like other sand in this region, contains more or less organic matter. The extreme wells are about four hundred feet apart in an easterly and westerly direction, and two hundred feet in a northerly and southerly direction. Water from the wells is pumped to a covered iron tank twenty-eight feet in diameter and one hundred feet high, and is distributed thence to the town. In order to aerate the water, the force main is carried vertically up

## PROVINCETOWN.

inside the tank to its top, and is provided with a wide flange over which the water falls in a thin sheet. The distributing mains are of cast iron; service pipes of wrought iron lined with cement.

Extended references to the character of this water, which differs from other ground waters in the State, may be found in the annual report of the State Board of Health for 1892, pages 41-44 and 214-218.

\* October.

† November and December.

NOTE to analyses of 1893; Iron, .0153. Odor, generally distinctly vegetable and often grassy or sweetish, becoming somewhat stronger on heating.—The samples were collected from the brook above the reservoir.

*Microscopical Examination.*

The greatest number of organisms per cubic centimeter found in any of the samples collected in 1893 was 198, in April; the smallest number, 1, in March; and the average, 62.

## QUINCY.

*Chemical Examination of Water from the Storage Reservoir, Quincy.*

Iron in the first sample, .0115; in the second sample, .0500. Odor, faintly vegetable, becoming much stronger on heating.—The samples were collected from the reservoir about fifty feet from the gate-house at a point where the water was about thirty feet deep; the first sample was collected near the surface and the last near the bottom.

NOTE to analyses of 1893; Odor faintly mouldy or unpleasant, often none; in June and July disagreeable. — The samples were collected from a faucet at the pumping station.

## READING.

This water offers a good instance of the effect of a marshy soil on the character of the water percolating through it. The organic matter of the soil consumes the free dissolved oxygen in the water and reduces the insoluble iron salts to the condition of protoxide, so that iron passes into solution in the water. On exposure of the water to the air the iron is again oxidized, forming first a precipitate which gives the water a milky appearance and ultimately settles as a rusty sediment. Conditions in some respects similar to those at Reading are found in Provincetown, Bradford and Watertown, and were found in the test wells at Attleborough (see Twenty-third Annual Report, 1891).

The determinations of turbidity and color in waters of this kind do not have the same significance as in surface waters, but they are, nevertheless, of interest as showing a condition which the water may assume, and are therefore given in the table.

WATER SUPPLY OF REVERE AND WINTHROP. — REVERE WATER COMPANY.

This company obtains part of its supply from wells in Revere and part from wells in Saugus. During the year 1893 there was a sudden and very decided increase in the quantity of chlorine present in the water of the wells located at Revere, as shown by the analyses on the following page, accompanied by a corresponding increase in residue on evaporation and in hardness. This deterioration in the char-

**REVERE.**

acter of the water is due to the presence of a small amount of sea water in the water of these wells, which are located only a comparatively short distance from salt water.

SALEM AND BEVERLY.

WATER SUPPLY OF SALEM AND BEVERLY.

The advice of the State Board of Health to the city of Salem, with reference to increasing the joint water supply of Salem and Beverly, by diverting the waters of Longham Meadow Brook and of the brook flowing from Beaver and Norwood's Ponds into Wenham Lake, may be found on page 47 of this volume. Analyses of samples of water collected from the proposed sources are given in the tables on pages 277 and 278.

Iron in the first sample, .0650; in the next two, .0500 each; in the fourth, .0600; in the last, .0150. Odor of the first three samples distinctly vegetable and of the first one also disagreeable. Of the last two samples, No. 10132 had a very faintly vegetable odor and No. 10133 none. — Nos. 10072 and 10132 were collected from the brook flowing from Norwood's Pond; No. 10073, from the brook flowing from Beaver Pond; Nos. 10074 and 10133, from Longham Meadow Brook just above the point where it is joined by the brook flowing from Norwood's Pond.

## WATER SUPPLY OF SAUGUS.

(See *Lynn*.)

## SCITUATE.

The advice of the State Board of Health with reference to taking a water supply for the village of Scituate Harbor in the town of Scituate, from the ground in the vicinity of Satuit Brook, may be found on page 50 of this volume. An analysis of a sample of water from the flowing test well, referred to in the communication of the Board, is given below.

## SCITUATE.

Odor none. — The sample was collected from a flowing test well in a meadow near Willow Street about three hundred feet east of the railroad.

*Microscopical Examination.*

No organisms.

## WATER SUPPLY OF SHARON. — SHARON WATER COMPANY.

The reply of the State Board of Health to an application of the Board of Health of Sharon for advice with reference to the possible pollution of the water supply of the town under existing conditions, and as to the best practicable method of assuring its purity in the future, may be found on page 51 of this report.

Odor, none. — The sample was collected from a faucet at the pumping station.

*Microscopical Examination.*

No organisms.

## WATER SUPPLY OF SOMERVILLE.

(See *Boston, Mystic Works.*)

## WATER SUPPLY OF SOUTHBRIDGE. — SOUTHBRIDGE WATER SUPPLY COMPANY.

The advice of the State Board of Health to the Southbridge Water Supply Company relative to increasing its supply by the

**SOUTHBRIDGE.**

construction of an additional storage reservoir about one mile south of the present upper reservoir, and as to improving the existing supply; also, at a subsequent date, with reference to increasing its supply by taking water from a proposed storage reservoir on Hatchet Brook, may be found on pages 51-53 of this volume. Analyses of samples of water collected from the present sources of supply and from Hatchet Brook and its tributaries are given in the following tables.

*Chemical Examination of Water from the Lower Reservoir of the Southbridge Water Company.*

Odor of the first sample, none; of the second sample, distinctly unpleasant, disappearing on heating. — The first sample was collected from a faucet in Southbridge supplied from the spring; the last, directly from the spring. The spring is located a short distance below the lower reservoir of the Southbridge Water Company, in the valley of the brook upon which the reservoirs of this company are built, and is used as a source of supply for several families.

## WATER SUPPLY OF SPRINGFIELD.

During the summer and autumn of 1893 the amount of water furnished by the Ludlow Receiving Basin and its tributary canals was insufficient for the supply of the city, and, to make up the deficiency, water was taken from the old Ludlow Reservoir and from Chapin Pond, which is situated near the main pipe leading to the city. It happened somewhat inopportunistly that, with a view to improving the character of the water, the old Ludlow Reservoir had been drawn off during the latter part of 1892 and was empty on, and for several months after, the first of January, 1893. While the reservoir was empty, a new waste-gate was put in at the Cherry Valley dam in order to make it possible to waste water from the bottom of this reservoir in the future, when desirable, and at the completion of this work on May 9, 1893, the filling of the reservoir was begun again; but the amount of water collected during the remainder of the year was so small that the water in the reservoir did not rise high enough to flow through the pipe beneath the cut-off dam into the Ludlow Receiving Basin, and in order to use the water which had accumulated, for the supply of the city, it was necessary to pump it into the basin. Pumping was begun on Aug. 22, 1893, and continued until October 24, the total quantity pumped being 63,000,000 gallons.

Chapin Pond is located in a sandy plain in the southwesterly part of Ludlow, and is said to have an area of about thirty acres

## SPRINGFIELD.

and a considerable depth. It has no visible inlet or outlet and is supplied with water which percolates into it from the sandy territory by which it is surrounded. The lowering of the water in the pond by pumping doubtless makes available a considerable quantity of water stored in the ground about it. Between Aug. 7 and Oct. 28, 1893, a total of 164,000,000 gallons of water were pumped from this source. An analysis of the water of Chapin Pond is given with the analyses of samples of water from the other sources of supply in the tables below.

Iron, .0102. Odor, generally distinctly vegetable, frequently grassy, sometimes none. In September the odor was strongly vegetable and mouldy. — The samples were collected from the basin in the vicinity of the gate-house. When the September and October samples were collected water was being pumped into this basin from Ludlow Reservoir.

\* These analyses were made by Prof. William R. Nichols, for the city of Springfield, from samples collected about once a week, between July 1, 1876, and Sept. 30, 1877.

† June to December.

‡ January to September.

§ May to December.

NOTE to analyses of 1893; Iron, .0133. Odor, vegetable, rarely mouldy or unpleasant; on heating the odor is generally stronger. — The samples were collected from the reservoir at depths of one to six feet beneath the surface, generally near the outlet. In July and August the samples were collected near the center of the reservoir.

This reservoir was empty at the beginning of the year and began to fill again on May 9. For record of heights of water on dates when samples of water were collected for analysis, see page 289.

## SPRINGFIELD.

*Microscopical Examination of Water from Ludlow Reservoir.*

[Number of organisms per cubic centimeter.]

Iron, .0069. Odor, of the first sample, none, becoming distinctly vegetable on heating; of the second and last samples, distinctly vegetable and unpleasant; of the third sample, faintly vegetable. The odors of the last three samples were unchanged by heating. — The first and last samples were collected from faucets in the pumping station, and represent water from the lake; the second sample, directly from the lake near the pumping station.

Odor, none. — The first two samples were collected from Smith Brook at the second road crossing above West Street, and the last sample from Lulu Brook, at the first road crossing above Onota Lake.

*Microscopical Examination.*

No. 15633 was not examined. An insignificant number of organisms was found in each of the other samples.

## STOUGHTON.

near the well. The watershed of the brook, above a point opposite the well, has an area, as measured from the State map, of 1.83 square miles. Of this area, fully one-third contributes to the supply of Muddy Pond. This portion of the watershed is an elevated and generally level gravelly tract, which contains a great many depressions from which there is no outlet, and the portion of the rainfall which is not evaporated sinks into the ground and reappears in and around Muddy Pond in the form of springs. The remainder of the watershed drains through Leonard Brook and enters Muddy Pond Brook a short distance below the pond.

The pond is about three hundred feet in diameter and is surrounded by swampy land, at the edge of which most of the springs appear.

The well is six feet in diameter and is said to be thirty-nine feet in depth. It is lined with brick work, the portion near the bottom being laid without mortar. Just below the well a puddle cut-off wall was constructed across the valley of the brook, two hundred and forty feet in length and forty feet in depth. The excavation for this wall is said to have been through six feet of clay, thirty to thirty-two feet of gravel, and two to four feet of hard pan. On the upper side of the wall, just above the hard pan, six lines of four-inch tile pipes were laid to the collecting well. Between the well and Muddy Pond, at a point five hundred to six hundred feet above the well, a dam was constructed to flow an area of 34.3 acres to an elevation about twelve feet above the level of the brook at the collecting well. The pond and swampy land before mentioned were included in the area to be flowed. It was thought that this reservoir would increase the supply from the well, but as it was found upon trial that it did not, and the water was of such character that it was not suitable for use if taken directly from the reservoir, it was abandoned.

From the collecting well a twelve-inch cast-iron pipe, 4,263 feet in length, conveys the water to a pump well at the pumping station, which is located on the right or easterly bank of the brook, just above Central Street. The pipe is turned down at both ends and was intended to act as a siphon when the water in the collecting well was lower than the pipe. The pump well is a water-tight wrought iron tank, six feet in diameter and twenty-six feet in depth, and from it water is pumped to the town and to the open iron tank formerly used in connection with the old source of supply.

**STOUGHTON.**

With a view to filtering the water taken from the brook, a small filter, having an area of about one hundred square feet, was constructed near the collecting well. The filter contains five feet in depth of sand and gravel of various degrees of fineness, the coarser material being at the bottom of the filter and the finer at the top. Water from the brook can be turned upon the filter to a maximum depth of two feet.

After it was found that the collecting well would not furnish enough water for the town, application was made to the State Board of Health for advice relative to taking a new source or devising some method of obtaining a larger supply from the present plant. The reply of the Board to this application may be found on page 55 of this volume.

Iron, .0065. Odor, distinctly vegetable. — The sample was collected from a faucet at the pumping station, at a time when water was being taken from the brook.

*Microscopical Examination.*

Diatomaceæ, *Meridion*, 1; *Pinnularia*, 1; *Synedra*, 20. Fungi, *Crenothrix*, 3. Miscellaneous, *Zoogloæa*, 3. Total, 28.

## WATER SUPPLY OF SWAMPSCOTT AND NAHANT — MARBLEHEAD WATER COMPANY.

The great variation in the quantities of chlorine, total residue, and hardness in this water, is due to the presence of a small quantity of sea water, at times, in the water of some of the wells from which the supply of this company is drawn.

## SWAMPSCOTT AND NAHANT.

*Chemical Examination of Water from the Wells of the Marblehead Water Company, Swampscott.*

\* June to December.

† January to May.

‡ October.

NOTE to analyses of 1893; Odor, of No. 10226, faintly earthy; of No. 10378, faintly disagreeable, becoming fainter on heating; of the remaining samples, none. — The samples were collected from a faucet at the pumping station.

*Microscopical Examination.*

A very few organisms were found in the samples collected in April, May, June, October and November. In the remaining samples no organisms were found.

## TAUNTON.

## WATER SUPPLY OF TAUNTON.

Works were nearly completed during the past year for taking an additional supply of water for the city of Taunton from Elder's and Assawompsett ponds in Lakeville. The design of the new works was governed to a large extent by a desire to utilize the more valuable features of the existing works, consisting of a pumping station, in which a new pump had recently been placed, on the bank of the Taunton River, above Taunton, and a filter-basin near the river. The direct-pumping system is used in supplying the city.

The principal features of the new works are a thirty-inch cast-iron pipe about seven miles long for conveying the water by gravity from Elder's Pond to the old pumping station, and a new pumping station and a twenty-four-inch cast-iron force main nearly 6,000 feet in length for lifting and conveying water from Assawompsett Pond into Elder's Pond.

Elder's Pond has an area of 145 acres, a maximum depth of 54.5 feet, and a practically unpopulated, sandy watershed of 195 acres, exclusive of the pond. Its surface is about eighty-six feet above high tide at Taunton, seventy-two feet above the sill of the old pumping station, and thirty-five feet higher than Assawompsett Pond.

Assawompsett Pond, with the exception of the Watuppa lakes the largest body of fresh water in the State, has an area of 2,691 acres, and is the lowest of a chain of ponds comprising also Long, Great Quittacas and Elder's Pond. The total area of the four ponds is 5,652 acres. The area of the watershed above the outlet of Assawompsett Pond, exclusive of the water surfaces of the ponds, is 39.8 square miles.

The water of Assawompsett Pond ranks next to that of Elder's Pond in quality, and the arrangement of the works by which this water would be turned into Elder's Pond before being sent to the city is thought to insure its improvement, both by mingling with the better water in Elder's Pond and by the opportunity afforded it for bleaching while stored in this pond. A suggestion with regard to the further improvement of the water of Assawompsett Pond by filtering it through the natural ground before it entered Elder's Pond is contained in the advice of the Board to the city of Taunton relative to these sources of additional supply, which may be found in the annual report of the State Board of Health for 1891 (page 32).

## TAUNTON.

Provision has been made at the pumping station for conveying the water of Elder's Pond directly to the pumps, to the filter-basin or to the old twenty-inch force main leading to the city. By means of the connection last mentioned water could be supplied under a light pressure to portions of the city by gravity in the event of any accident to the pumps. A twenty-inch blow-off discharging into the Taunton River has also been provided.

When the new works are put in operation the use of the Taunton River as a source of supply will be discontinued, although water may still be drawn from the filter-basin. It is proposed, however, to retain the pipe connecting with the river for use in cases of emergency.

*Chemical Examination of Water from the Filter-Basin of the Taunton Water Works.*

\* June to December.

Note to analyses of 1893; Iron, .0278. Odor, distinctly vegetable and grassy, very rarely unpleasant. — The samples were collected from a faucet at the pumping station while pumping. Water from the Taunton River is admitted directly to the filter-basin whenever the yield of the latter is insufficient for the supply of the city.

## TAUNTON.

*Microscopical Examination of Water from the Filler-Basin of the Taunton Water Works.*

Iron, .0008. Odor of the first sample, none; of the others, vegetable. — The samples were collected from the pond in the vicinity of the gate house of the Taunton Water Works.

*Microscopical Examination.*

The total number of organisms per cubic centimeter found in each of these samples was as follows: No. 10186, 19; No. 10581, 135; No. 11520, 19.

Iron, .0006. Odor, distinctly vegetable. — The samples were collected from the pond near the surface and 300 to 400 feet from the shore.

*Microscopical Examination.*

The total number of organisms per cubic centimeter found in each of these samples was as follows: No. 10187, 362, chiefly *Dinobryon*; No. 10589, 51, chiefly *Melosira*; No. 11519, 105, chiefly *Asterionella*.

## WATER SUPPLY OF UXBRIDGE.

The advice of the State Board of Health to the town of Uxbridge with reference to an additional water supply which it was proposed to take from either Seagrave or Cold Spring Brook in Uxbridge or from Mendon Pond in Mendon, together with the opinion of the Board as to the relative merits of these sources, can be found on page 57 of this volume. Further reference to Mendon Pond as a source of water supply for Mendon and Uxbridge can be found on

## UXBRIDGE.

page 39 of this volume, and on page 46 of the annual report of the Board for 1892.

Analyses of samples of water from these sources are given in the following tables.

*Chemical Examination of Water from Cold Spring and Seagrave Brooks, Uxbridge.*

Iron in the first sample, .0000; in the last, .0050. Odor of the first sample, distinctly vegetable; of the last, faintly vegetable, becoming stronger on heating — The first sample was collected from Cold Spring Brook at the point where it is crossed by the Old Douglas road, between Uxbridge and East Douglass; the last sample, from Seagrave Brook at the point where it was proposed to divert the water, a little less than a mile above its junction with Emerson Brook.

\* Where more than one sample was collected in a month the mean analysis for that month has been used in making the average.

Iron, .0043. Odor, generally faintly vegetable or none, rarely mouldy or disagreeable; on heating, the odor is somewhat stronger and frequently mouldy. — The samples were collected from the pond within three feet of the surface, with the exception of Nos. 10665 and 10930, which were collected at depths of fourteen and one-half and twelve and one-half feet respectively beneath the surface.

\* Where more than one sample was collected in a month the mean analysis for that month has been used in making the average.

† June to December.

‡ January to October.

§ January, March and June.

|| Three in October.

¶ May and November.

NOTE to analyses of 1893; Iron, .0109. Odor, generally faintly vegetable, rarely none; in June, disagreeable; on heating, the odor is generally considerably stronger, and in the April sample was oily or fishy. — The first sample was collected from the pond; the remaining samples, from faucets.

## WALPOLE.

The advice of the State Board of Health to the town of Walpole with reference to taking a water supply from the ground near the Neponset River, or tributaries thereof, within the limits of the town, may be found on page 60 of this volume. Analyses of samples of water collected from tubular test wells near the Neponset River are given in the following table.

**WALPOLE.***Chemical Examination of Water from Tubular Test Wells near the Neponset River, in Walpole.*

[Parts per 100,000.]

| 10271   | Apr. 19             | None.       | Cons. sand. | 0.00   | 5.70                    | .0002    | .0004         | .36       | .1000       | .0000     | .0146            | 1.1       | .0110 |

Odor, none. — The samples were collected from tubular test wells on the easterly side of the Neponset River about one mile south of the village of Walpole. The first sample was collected from Well No. 1, twenty feet in depth, located about seventy-five feet from the Neponset River and about seven hundred and fifty feet down stream (northerly) from the mouth of Low Brook; the last sample, from Well No. 2, thirty feet in depth, located about ninety feet from the Neponset River and about fifteen feet northerly from Low Brook.

*Microscopical Examination.*

No. 10270. No organisms.

No. 10271. Diatomaceæ, *Synedra*, 1.**WATER SUPPLY OF WALTHAM.**

Much trouble has been caused in recent years by the rapid growth of certain low forms of vegetation in the filter-basin and well of the Waltham water works, and with a view to preventing this growth the filter-basin and well were covered in the autumn of 1893. The work was completed before the November and December samples were collected, and the improvement in the quality of the water may be seen by examining the tables of analyses which follow. Reference is also made to the character of the well water in a reply of the State Board of Health to the Water Commissioners of Waltham, which can be found on page 61 of this volume. The distributing reservoir has not been covered, so that the quality of the portion of the water supply of the city which passes through it is affected as in the past by the abundant growths of microscopic organisms.

The filter-basin before being covered had the shape of a rectangle with one corner cut off, and an area of about ten thousand square feet. The well, which is located in the centre of the filter-basin, is forty feet in diameter and is covered with a dome made of flat tiles laid in Portland cement. The portion of the filter-basin outside of the well is covered with a series of brick arches. The shape and size of the filter-basin were not materially changed.

\* Where more than one sample was collected in a month the mean analysis for that month has been used in making the average.

† June to December.

‡ January to May.

§ July.

NOTE to analyses of 1893; Odor of No. 9930 none, becoming distinctly aromatic after standing one day; of No. 10100, distinctly aromatic; of No. 10171, very faintly vegetable; of Nos. 10323 to 10652, inclusive, unpleasant or disagreeable; of all other samples, none. The odor in nearly every case disappeared on heating. — The samples were collected either from a faucet at the pumping station while pumping, or from the filter-basin. The November and December samples were collected after the covering of the filter-basin had been completed.

\* Where more than one sample was collected in a month the mean analysis for that month has been used in making the average.

† June to December.

‡ January to May.

§ February.

|| May.

NOTE to analyses of 1893; Odor, generally faintly aromatic or unpleasant or none; on heating, the odor is stronger and occasionally disagreeable or fishy. — The samples were collected from the reservoir at the gate-house, with the exception of the last two, which were collected from the reservoir at the side opposite the gate-house.

## WATER SUPPLY OF WARE.

The works for collecting water for this town were enlarged in the latter part of 1893 by sinking twelve tubular wells in the valley of Muddy Brook, about 500 feet north of the large well, which was previously the only source of supply for the town; and by constructing a well nine feet in diameter and six feet in depth at the

site of a large spring located near the tubular wells. The tubular wells are located within an area approximately 150 feet in length and somewhat less than 100 feet in width. The depth of the wells varies from twenty-eight to thirty-nine feet and averages thirty-four feet. Water from the wells and spring flows by gravity through a twelve-inch pipe to the main well.

## WATERTOWN AND BELMONT.

WATER SUPPLY OF WATERTOWN AND BELMONT—WATERTOWN  
WATER SUPPLY COMPANY.

The Watertown Water Supply Company made extended investigations in 1893 with reference to obtaining an additional supply of water from the ground in the vicinity of its pumping station and examined other sources. The company also made an application to the State Board of Health for its advice relative to the improvement of its supply, and many of the analyses given in the following tables were made during the investigations of the Board, but at the end of the year the matter was still under consideration.

The investigations showed that the water collected by the original filter-gallery and by a system of tubular wells northwesterly from the pumping station was nearly the same in character as during the earlier years of the operation of the works, but water collected from the ground in an easterly direction from the pumping station has to a greater or less degree the usual characteristics of a water containing iron. The most successful results were obtained from some six-inch wells located about 950 feet southeast of the pumping station, and about forty feet from the river. A temporary pump was connected with these wells in the summer of 1893, and during the summer and autumn a material addition to the water supply was obtained from this source. The last three analyses in the table on page 314 are of samples of water from these wells. It is probable that most of the water which they supplied came by filtration from the river, and although it contained iron and manganese and did not show the high degree of chemical purification which water attains when it filters a sufficient distance through the ground under favorable circumstances, it was rendered very nearly pure, bacterially, by the filtration.

The table on page 315 contains the analyses of water from two deep tubular wells, one located near the pumping station, and the other in the centre of the main village of Watertown. Neither of these deep wells furnished any large quantity of water nor was the quality of the water satisfactory, and no part of the water supply of the town is now taken from them.

\* June to December.

† January to May.

‡ August.

§ September to December.

NOTE to analyses of 1893; Odor, generally none, occasionally mouldy and unpleasant. — The samples were collected from a faucet at the pumping station while pumping.

In the above table the samples with the higher amounts of iron became turbid and colored by the precipitation of the iron by oxidation on exposure to the air.

\* This sample contained also 0.1760 part manganese.

Odor of the first three samples, none; of the last three, mouldy or unpleasant; on heating, the odor of the second sample was distinctly vegetable, and of the last two, faintly vegetable. — The first sample was collected from a group of tubular wells located a short distance northwest of the pumping station; the second and third, from a flowing well two inches in diameter, located about one thousand feet southeasterly from the pumping station and about seventy-five feet from Charles River; the last three, from six-inch tubular wells, located about nine hundred and fifty feet southeast of the pumping station and about forty feet from the river. Water was pumped from these six-inch wells into the filter-gallery in the summer and autumn of 1893.

## WATERTOWN AND BELMONT.

*Microscopical Examination.*

No. 10418. Diatomaceæ, *Melosira*, 3; *Tabellaria*, 2. Fungi, *Crenothrix*, 34. Miscellaneous, *Zoëglæa*, 24. Total, 63.

No. 10667. Fungi, *Crenothrix*, 10. Miscellaneous, *Zoëglæa*, 2. Total, 12.

No organisms were found in the remaining samples.

*Bacterial Examination.*

Three samples of water collected on June 30 from the two-inch flowing well from which Nos. 10418 and 10550 were collected, contained an average of five bacteria per cubic centimeter, the highest number found being seven and the lowest two.

Three samples of water collected on July 17 from the six-inch tubular wells contained an average of four bacteria per cubic centimeter.

These wells were examined again on October 23, two samples being collected, each of which contained four bacteria per cubic centimeter.

\* All determinations of this sample were made on the filtered water.

Odor of the first sample, faintly earthy; of the last, none. — The first sample was collected from a tubular well eight inches in diameter and about 250 feet in depth, located about fifty feet south of the pumping station of the Watertown Water Supply Company; the last, from a deep tubular well located near the centre of the main village of Watertown and near the railroad station. It is said that 160,000 gallons of water were pumped from the latter well in the twenty-six hours previous to the collection of the sample.

*Microscopical Examination.*

No organisms.

## WATER SUPPLY OF WEBSTER.

*Description of Works.* — Population in 1890, 7,031. The works are owned by the town and water was introduced Jan. 1, 1894. The town had been supplied for many years previous to this time from works owned by H. L. Slater, the source of supply being Lake Chaubunagungamaug. The new source of supply is a well twenty-five feet in diameter and thirty feet in depth, located on the northwesterly side of the lake, about 200 feet from the shore. The wall of the well is made of stone, laid without mortar, for a height of three feet above the bottom, and above this level also of stone,

**SPRINGFIELD.**

*Microscopical Examination of Water from Ludlow Reservoir,  
Springfield.*

The number of organisms found in the samples of water collected from Ludlow reservoir in the months of January, February and June was insignificant. In March, April and May the samples contained respectively 3,850, 1,065 and 1,590 organisms per cubic centimeter, consisting almost wholly of Dinobryon or Dinobryon cases. The results of the microscopical examination of samples collected during the remainder of the year are given in the following table :—

*Microscopical Examination of Water from Ludlow Reservoir.*

[Number of organisms per cubic centimeter.]

[illegible]

## WESTBOROUGH.

## WATER SUPPLY OF WESTBOROUGH.

The advice of the State Board of Health to the town of Westborough, with reference to increasing the supply of filtered water from the Lower Sandra Basin by facilitating the filtration of water from the Upper Basin into it through the intervening ground may be found on page 63 of this volume.

## WATER SUPPLY OF WESTBOROUGH INSANE HOSPITAL, WESTBOROUGH.

\* June to December.

† January to May.

‡ July, two samples.

NOTE to analyses of 1893; Odor of the first sample, none, becoming distinctly vegetable and grassy on heating; of the second sample, offensive, disappearing on heating; of the remaining samples, none. — The samples were collected from a faucet at the pumping station while pumping.

Iron in considerable amount is characteristic of the water of these wells. It oxidizes promptly on exposure to the air and precipitates, causing first a milky turbidity and then a rusty precipitate. Somewhat similar conditions exist in the water supplies of Reading, Bradford and other places.

*Microscopical Examination.*

The organisms found in these samples in 1893 were chiefly Zoöglas, the greatest number, 124, being present in January, and the smallest, 6, in May.

## WESTFIELD.

Iron, .0098. Odor of the first sample, distinctly mouldy; of the second, distinctly vegetable and sweetish; of the last, faintly vegetable. — The samples were collected from the lower or distributing reservoir in Montgomery. Water flows from the storage to the distributing reservoir, a distance of a little more than two miles, in the open channel of the brook, falling more than 400 feet in its course from the storage reservoir. The lower reservoir has a drainage area of two and one-quarter square miles in addition to that of the storage reservoir.

## WEST SPRINGFIELD.

## WATER SUPPLY OF WEST SPRINGFIELD.

The town of West Springfield extended its works in 1893 with a view to supplying water to the village of Mittineague, which is situated at too great an elevation to be supplied with water from the existing works. The new source of supply is a well twenty-five feet in diameter and fourteen feet deep, located at the Craig Spring, a short distance below the storage reservoir. The well is supplied in part by the numerous springs in its vicinity, the water of which is collected by means of small pipes into a main pipe which carries it to a settling well and thence to the main well. Water is pumped from this well by means of a windmill to a tank at Mittineague. The advice of the State Board of Health to the town of West Springfield relative to an additional water supply for the town may be found on page 65.

Iron, .0041. Odor of the first and fourth samples, distinctly vegetable and grassy, becoming faintly vegetable on heating; of the second and third, none; of the last two, very faintly vegetable. — The first sample was collected from Bear Hole Brook, in the northwesterly part of West Springfield, near the Massasoit Spring, and about two miles below the outlet of Ashley Pond; the second, from the Massasoit Spring; the third, from Leonard Brook in Agawam, about half a mile above its mouth. This brook is a very small tributary of the Westfield River, and enters it from the south at the first bridge above its mouth. The fourth sample was collected from Lathrop Brook in West Springfield, a small tributary of Block Brook, entering it about a mile and a half from its mouth; the fifth sample from Hyde Brook in West Springfield, at the point where it is crossed by a road leading from Mittineague to Prospect Hill; and the last sample from the Craig Spring, which is now used to supply the village of Mittineague.

\* June to December.

† January to May.

‡ July.

NOTE to analyses of 1893; Iron, .0182. Odor of the first sample, distinctly vegetable; of the second and last samples, faintly vegetable; of the third sample, none.—The samples were collected from faucets in the town.

*Microscopical Examination.*

Very few organisms were found in any of these samples.

## WATER SUPPLY OF WHITMAN.

The advice of the State Board of Health to the town of Whitman, with reference to taking an additional supply of water for that town from ponds in Pembroke, Hanson and neighboring towns, may be found on page 67 of this volume.

For analyses of samples of water from the various ponds mentioned in the reply of the Board, see *Abington, Hanson and Pembroke*. Analyses of samples of water from the present sources of supply are given below.

*Chemical Examination of Water from the Filler-Gallery of the Whitman Water Works.*

\* June to December.

NOTE to analyses of 1893; Iron, .0078. Odor, distinctly vegetable and frequently unpleasant; on heating, the odor is generally stronger and frequently also disagreeable. — The first two samples were collected from the pond about one hundred feet from the shore near the pumping station of the Woburn Water Works; the remaining samples from the pond near its outlet. The samples were collected about one foot beneath the surface.

## WOBBURN.

*Microscopical Examination of Water from Horn Pond, Woburn.*

[Number of organisms per cubic centimeter.]

## WORCESTER.

## WATER SUPPLY OF WORCESTER.

During the past year the raising of the dam of the Holden storage reservoir has been completed and the capacity of the reservoir increased by nearly 300,000,000 gallons. The work consisted of strengthening the dam on the lower side by widening its base and increasing its height to a level of ten feet above the old dam, allowing the latter to form a berme in the completed structure. The area of the reservoir is now 149.5 acres, and its capacity 742,000,000 gallons. Its greatest depth is 30.1 feet and its average depth about 15.2 feet. The area newly flowed has been prepared by removing the trees and bushes and much other objectionable material, and by covering the swampy places with gravel.

\* June to December.

NOTE to analyses of 1893; Iron, .0195. Odor, generally faintly vegetable, occasionally unpleasant, frequently none; on heating, the odor is much stronger and very frequently unpleasant. — The samples were collected from the reservoir near the gate-house, one foot beneath the surface.

## EXAMINATION OF RIVERS.

---

## EXAMINATION OF RIVERS.

---

During the year 1893 regular monthly examinations were made of the waters of the Blackstone, Merrimack, Nashua (below Fitchburg), Neponset, Housatonic and Taunton rivers, and during the latter portion of the year, in connection with the investigations for a metropolitan water supply, of the Charles at South Natick, Deerfield, Nashua (above Clinton), and its tributaries, the Quinepoxet and Stillwater, Shawsheen and Ware rivers. A special examination has also been made of the tidal portion of the Charles River, which is a repetition of the examination of this stream made in 1893, and occasional examinations of other rivers in the State. Most of the results of these examinations will be found arranged alphabetically by rivers in the pages which follow; but some of them are given on preceding pages in connection with the examinations of water supplies, under the names of the towns where the samples were collected, as follows:—

|                                                                   | PAGE |

### BLACKSTONE RIVER.

The character of the water of the Blackstone River is closely related to the disposal of the sewage of the city of Worcester, and it is therefore of interest to note that during 1893 the capacity of the precipitation works for treating the sewage of this city has been greatly increased by the construction of new precipitation tanks and other additions to the works, which were used for the first time on July 15. A full description of the works as originally constructed, and the results of a special examination of the works and the river during one week in 1891, can be found in the annual report of the State Board of Health for that year (pages 267-295).

**BLACKSTONE RIVER.**

Six precipitation tanks were constructed at first, and ten new tanks of the same area as the old ones were added in 1893. The new tanks, however, are longer and narrower than the others, their dimensions being 166.67 feet long, 40 feet wide and 5 feet deep below the bottom of the inlet and outlet channels. When in operation the tanks are filled to a depth of about six and a half feet, and with this depth they contain about 5,000,000 gallons of sewage.

For the information of those who are not familiar with the previous history of these works it may be stated that the sewage of Worcester is not taken directly from the sewers to the precipitation works, but is first discharged into Mill Brook; and it is the mingled sewage and brook water which is conveyed to the precipitation works and treated. Before the recent enlargement of the works only a small part of the flow of this brook could be treated, and the remainder of the sewage went directly into the Blackstone River; but the new works, which are said to have a nominal capacity of 15,000,000 gallons per day, and to be capable of treating with very good results a somewhat larger quantity, are thought to be of sufficient capacity to take the whole flow of the brook under all ordinary conditions.

The Worcester sewage is unusual in its character, both on account of its dilution by the brook water and because of the large amount of iron salts (mainly sulphate of iron) which it receives from time to time every working day from the large iron and wire works in the city. Lime has been the only precipitant added to the sewage in 1893, and when iron is present in the sewage a satisfactory precipitation results. The sewage, however, contains iron only a part of the time, and it is therefore the custom to store the sewage containing iron in two of the old precipitation tanks so that it can be used to mingle with the sewage subsequently arriving and containing no iron, and in this way form a satisfactory precipitate at all times.

Owing to the increase in the quantity of sewage treated it has been necessary to increase the capacity of the tanks in which the chemicals are mixed, and the old mixers have therefore been replaced by two new iron-lined mixers, each sixteen feet long, eight feet wide and three and a half feet deep. Lime is turned into the mixers from the floor above, and the mixture with water is accomplished by means of compressed air discharged through perforated pipes in the bottoms of the mixers. The lime mixture is conveyed

## BLACKSTONE RIVER.

through six-inch iron pipes to the sewer at a point ninety feet above the screens, instead of being discharged as formerly below the screens. This change was made in order to insure a more thorough mixing of the lime with the sewage previous to subsidence. The amount of lime necessary to make the sewage alkaline is determined by frequent tests with phenolphthalein.

The continuous process of precipitation is used, the sewage flowing through the different tanks in order, and the effluent being discharged continuously from the last one. The fall of the effluent is utilized, by means of a turbine wheel, to furnish power at night for lighting the works by electricity, and in the day time for pumping the sludge by means of a Shone ejector to sludge beds located near the Blackstone River. These beds at the present time cover an area of about fourteen acres. During 1893 nearly all of the sludge was disposed of to farmers for use as a fertilizer.

During the year ending Nov. 30, 1893, 1,795,000,000 gallons of sewage were treated and 1,105 tons of lime were used, making the amount of lime 1,232 pounds per million gallons of sewage. The amount of solid matter removed from the water during the year amounted to 2,360 tons.

The Worcester precipitation works have always been very intelligently operated under the direction of skilled chemists and engineers, and the following quotations from the annual report of the superintendent of sewers for the year ending Nov. 30, 1893, will be of interest as indicating the manner in which the work is carried on and the results obtained in the treatment of sewage since the works have been enlarged.

“From the first day the plant was operated, June 25, 1890, continued experiments have been made; at first, these were wholly mechanical and at random, but it was soon found that a systematic study of the whole problem must be made if the work was to be successful. Accordingly a well-equipped chemical laboratory has been provided and the problems met in actual manipulation are made subjects for special investigation. That this move has been productive of good is shown by the reduction of from thirty to fifty per cent. in the cost of chemicals used per million gallons of sewage treated.

Analyses of sewage and effluent are made daily. The samples for analysis are each composed of twenty-four portions taken hourly. Thus, by averaging results for several days, an effluent is obtained corresponding to

**BLACKSTONE RIVER.**

the sewage, and the per cent. of impurity removed is easily calculated. This per cent. removed is the indicator which shows the efficiency of the treatment.

Records of all analyses are kept in two forms; one simply the numerical tabulation, the other, a graphical illustration showing at a glance the constitution of the sewage and effluent, as well as the per cent. removed.

It will be noticed from accompanying table A, that the sewage dealt with is remarkably strong, considering that about half of it is water coming directly from North Pond. It is also interesting to note that the effluent contains only two and one-half parts per 100,000 of matter in suspension, and that, of this, only one and one-tenth parts are organic matter. Thus, by treatment, the organic suspended matter has been removed to the extent of 90.76 per cent. The total dissolved residue and the total and dissolved fixed residue are negative results, undoubtedly due to the large quantity of lime retained in solution in the effluent. From table A the result of the treatment of the sewage since July 15 can be followed by months, and the averages are given for the whole period."

"As the total volatile residue, the total albuminoid ammonia and the total oxygen consumed represent the amount of organic matter, these only are shown here :

|                                     |                          |
|-------------------------------------|--------------------------|
| Total volatile residue, . . . . .   | 51.06 per cent. removed. |
| Total albuminoid ammonia, . . . . . | 49.19 " " "              |
| Total oxygen consumed, . . . . .    | 33.27 " " "              |

The work done, as shown by these results, is very good, and should fully carry out the object of the plant, viz., not to transform sewage into a potable water, but to abate and finally terminate a nuisance to neighboring villages along the Blackstone River."

The results in 1893 are hardly as good as those obtained during the special examination for a week in 1891, but the difference is not very great, and the amount of chemicals used per million gallons during this year has been much less than during the week referred to.

The regular monthly examinations of the water of the Blackstone River have been continued as in previous years, and the results are given in the tables on pages 346-351. The first two tables contain, respectively, the results for each calendar year and for the six months of each year from June to November, from the time when the examinations were first begun in June, 1887, to the end of 1893.

Iron, .0474. Odor, generally musty, occasionally disagreeable or offensive. — The samples were collected from the canal leading from the upper dam of the Calumet Woolen Company to the mill just before the water passed the screens.

*Microscopical Examination.*

The number of organisms found in these samples varied from 143 to 3,360 per cubic centimeter and averaged 787, Zoöglæa being by far the most abundant and averaging 724.

## BLACKSTONE RIVER.

*Chemical Examination of Water from Blackstone River at Millville, Blackstone.*

Iron, .0452. Odor, generally musty, frequently disagreeable or offensive. — The samples were collected from the river just above the dam in the village of Millville.

*Microscopical Examination.*

The number of organisms found in these samples varied from 107 to 946 per cubic centimeter and averaged 294, Zoöglea being in most cases by far the most abundant and averaging 224.

CHARLES RIVER.

Regular monthly examinations of the water of Charles River above South Natick have been made during the last five months of 1893, and weekly examinations of the water at Ætna Mills and at a point about 2,000 feet below Galen Street bridge in Watertown were made from August 17 to October 26. An examination of the whole length of the tidal portion of the river by means of a series of chemical analyses of its water at high and low tide was made on August 17, 1893, during a course of neap tides occurring at a time when the flow of upland water was small. This examination of the tidal portion of the river is a repetition of a similar examination made in 1892, and fully described in the annual report of the State Board of Health for that year (pp. 282-289). Results of all of the analyses made during 1893 are given in the following tables: —

Iron, .0313. Odor, decidedly vegetable and musty or mouldy. — The samples were collected from the river about 2,000 feet below Galen Street bridge in Watertown, and about 400 feet below Barker's Starch Works. The point at which the samples were collected is in the tidal portion of the river, but it is doubtful if any salt water ever flows up to this point.

*Microscopical Examination of Water from Charles River about Two Thousand Feet below Galen Street Bridge, Watertown.*

Iron, .0092. Odor, faintly vegetable. — The samples were collected from the river about a mile above the bridge in the village of Shelburne Falls.

*Microscopical Examination.*

Average number of organisms, 83 per cubic centimeter.

## HOUSATONIC RIVER.

## HOUSATONIC RIVER.

Regular monthly examinations of the water of this river were made from March to the end of the year with a view to determining the extent to which the river is polluted by the sewage of the city of Pittsfield and other places upon its watershed. The samples were collected at New Lenox, which is distant about 3.9 miles by the river below the place where the sewage of Pittsfield is discharged into the stream. The drainage area of the river at New Lenox is 145.6 square miles, and the population on this area, by the census of 1890, was 23,300, equivalent to a population of 160 per square mile. Of the total population, 17,281 were in the city of Pittsfield.

**MERRIMACK RIVER.**

The usual monthly examinations of the water of this river opposite the intakes of the Lowell and the Lawrence Water Works have been continued during 1893, the detailed results of which may be found on pages 181 and 193 of this volume. A comparison of the analyses made at these two places during the year is given in the following table:—

## MERRIMACK RIVER.

*Table comparing the Analyses above Lowell with those above Lawrence, 1893.*

[Parts per 100,000.]

|                                                   | Color. | RESIDUE ON<br>EVAPORA-<br>TION. |                      | AMMONIA. |             |            |                 | Chlorine. | NITROGEN<br>AS |           | Hardness. |

In order to compare these results with similar ones obtained in previous years, another table is presented, which contains the increase in impurities as the water passes from a point above Lowell to Lawrence, as given in the last line of the above table, and the corresponding increase in previous years:—

*Increase in the Amount of Impurities in the Merrimack River Water, from a Point above Lowell to Lawrence, as determined by the Regular Monthly Examinations of Different Years.*

Iron, .0230. Odor, none. — The sample was collected from the river just above the Litchfield Spindle Company's dam at Shuttleville, at a time when the water in the river was very low. The dam at which the sample was collected is located about one and one-half miles above the main village of Southbridge.

*Microscopical Examination.*

Diatomaceæ, *Asterionella*, 2; *Navicula*, 5; *Synedra*, 4; *Tabellaria*, 1. Algæ, *Protococcus*, 12. Fungi, *Crenothrix*, 112. Miscellaneous, *Zoëglæa*, 11. Total, 147.

Iron in the first sample, .0130; in the second, .0110. Odor, distinctly vegetable and sweetish. — The first sample was collected from the river above the point where it is joined by Vine Brook; the last sample from the river about a quarter of a mile below the mouth of Vine Brook. These samples were collected in the vicinity of the upper end of a proposed storage reservoir surveyed by the city of Boston in 1886.

*Microscopical Examination.*

The total number of organisms per cubic centimeter found in the first sample was 155, consisting chiefly of *Crenothrix* and *Zoëglæa*; in the last sample 839 organisms were found, nearly all of which were *Crenothrix*.

## TAUNTON RIVER.

Regular monthly examinations of the Taunton River above Taunton have been made as in previous years, and the results are printed in connection with analyses of water of the Taunton water supply on page 296. In the following table analyses are given of the water of Mill River, a tributary of the Taunton, near its mouth. The sewage of a portion of the city of Taunton is discharged into this river.

## SUMMARY OF WATER SUPPLY STATISTICS.

At the end of 1893 the State contained 30 cities and 322 towns. The towns of Medford and Everett became cities on Jan. 2, 1893, thus causing the change in the number of cities and towns since the previous year.

A public water supply was introduced during this year for the first time into the towns of Chester, North Brookfield and Provincetown, increasing the number of places supplied to 146. In addition to the new supplies for the places named above, new sources have been substituted for old ones in Attleborough, Chicopee, Easthampton, Orange and Taunton. In many other places additional works of less importance have been constructed to increase the capacity of the sources of supply.

It has been found by experience that there is unusual danger when water is taken directly from a running stream into which sewage is discharged, and it is therefore worthy of note that of the works constructed during the year those at Taunton, Chicopee and Orange were built for the purpose of abandoning the use of polluted streams as sources of supply, while at Lawrence, although the Merrimack River is still used as a source, the whole of the water used is filtered through a filter having an area of two and one-half acres to remove the disease germs which may be in the river water.

At Lowell new works for taking water from the ground have been constructed, which furnish a portion of the supply of the city, but the greater portion still comes from the Merrimack River.

The following table gives a classification, by population, of cities and towns having and not having public water supplies Dec. 31, 1893. The populations are taken from the census of 1890:—

| POPULATION<br>(1890).    | Number of<br>Places of Given<br>Population<br>having a Pub-<br>lic Water<br>Supply. | Total<br>Population of<br>Places<br>in Preceding<br>Column. | Number of<br>Places of Given<br>Population<br>not having a<br>Public<br>Water Supply. | Total<br>Population of<br>Places<br>in Preceding<br>Column. |
|--------------------------|-------------------------------------------------------------------------------------|-------------------------------------------------------------|---------------------------------------------------------------------------------------|-------------------------------------------------------------|
| Under 500, . . . . .     | 0                                                                                   | 0                                                           | 28                                                                                    | 9,772                                                       |

From the totals given in the table it will be seen that, although but forty-one per cent. of the cities and towns in the State have a public water supply, yet the total population of places supplied represents 87.1 per cent. of the whole population of the State. In this estimate of the total population of municipalities supplied all of the inhabitants in them are included, and it consequently includes rather more than the actual number of persons to whom a public water supply is available; the difference, however, is not large. There are now but 6 towns having, by the census of 1890, a population exceeding 4,000, which are not provided with a public water supply. These are given in the following table:—

| TOWNS.                | Population in<br>1890. | TOWNS.                | Population in<br>1890. |
|-----------------------|------------------------|-----------------------|------------------------|
| Blackstone, . . . . . | 6,138                  | Winchendon, . . . . . | 4,390                  |
| Ipswich,* . . . . .   | 4,439                  | Rockport,* . . . . .  | 4,087                  |
| Millbury, . . . . .   | 4,428                  | Barnstable, . . . . . | 4,023                  |

\* Works for the supply of Ipswich and Rockport were begun in 1894.

In the following table the various water supplies are classified according to the dates when a fairly complete system of supply was first introduced into a city or town:—

| YEARS.                          | Number of<br>Places<br>Supplied. | YEARS.           | Number of<br>Places<br>Supplied. |

| 1890, . . . . .                 | 5                                |                  |                                  |

Of the 30 cities in the Commonwealth, 28, having a total population in 1890 of 1,355,849, own their water works; while 2, having a total population of 38,598, are wholly supplied by private companies. Of the 116 towns having public water supplies, 69,\* with a total population of 360,260, are supplied from their own works, while 47, with a total population of 194,748, are supplied by private companies. The total population in both cities and towns owning their works is 1,716,109, against 233,346 in those supplied by private companies.

The following table gives statistics with regard to the consumption of water in many of the cities and towns in this State. The populations for 1893, as given in the table, were obtained in a somewhat

\* The figures in this paragraph differ somewhat from corresponding figures on page 5, owing to information received after the first figures were printed that the control of water works in two towns had passed from private companies to the public authorities.

arbitrary manner by adding three-fifths of the increase in population from 1885 to 1890 to the population as determined by the census taken in the latter year. The daily consumption per *inhabitant*, obtained by dividing the average daily consumption by the total population of the city or town in 1893, is less than the amount per *consumer*, because there are some in all cities and towns who do not use the public water supply. This difference between the number of inhabitants and consumers accounts, to a large extent, for the low rate, per inhabitant, in some towns where works have been in operation only a short time, and in consequence water has not been generally introduced; also, in towns where there are villages to which the public water supply has not been extended; but, after making all due allowance for the varying proportion of water takers, there is still a very great difference in the amount of water used per person in different places, which it is very difficult to account for.

*Statistics relating to the Consumption of Water in Various Cities and Towns.*

\* May to December only.

† The growth of these places has been very rapid since 1890, and the estimates of population given by the superintendents of water works have therefore been used.

## RAINFALL.

The rainfall for the year 1893 was 0.56 inches in excess of the normal, but was very unevenly distributed. The greatest excess of rainfall occurred in February, May and December, while there was a deficiency in all the summer and autumn months with the exception of August, in which there was a slight excess. The effect of the distribution was to cause a very high flow in the streams in the spring months and a very low flow in the summer and autumn.

The average annual rainfall \* in Massachusetts, as deduced from long-continued observations in various parts of the State, is 45.14 inches. In the following table is given the normal rainfall for each month in the year, the rainfall for each month in 1893 and the departures from the normal. †

To enable the condition preceding the collection of samples of water in any part of the State to be understood, the following tables are presented, which give the daily rainfall in inches at nine stations scattered about the State : —

\* Including melted snow.

† This and subsequent tables of rainfall have been prepared from the records of the New England Weather Service.

*Daily Rainfall in Inches at Nine Places in Massachusetts, Geographically selected.*

January, 1893.

February, 1893.

## FLOW OF STREAMS.

The flow of the streams of the State during the year 1893, as indicated by the flow of Sudbury River, was a very little less than the average for the past nineteen years, but the distribution was very uneven. The flow was above the average in March, April and May, in the latter month being nearly twice as great as that recorded in the same month for any previous year, but in all the remaining months the flow was below the average, and from June to November, inclusive, was the smallest since 1887.

The effect of this distribution of the flow was the opposite of that of the previous year. In 1893 the drought was felt most by the cities and towns deriving their supply from large watersheds, with comparatively small storage, from which water usually runs to waste in the spring; while those communities taking their supply from large ponds fed by comparatively small watersheds experienced no unusual inconvenience, owing to the large amount of water collected during the spring months.

In order to show the relation between the flow of the Sudbury River during each month of 1893 and the normal flow of the same river, as deduced from fifteen years' observations from 1879 to 1893, inclusive, the following table has been prepared. The area of the watershed of the Sudbury River above the point of measurement is 75.2 square miles.

*Table showing the Average Monthly Flow of Sudbury River for the Year 1893, in Cubic Feet per Second per Square Mile of Drainage Area, also Departures from the Normal Flow.*

| MONTH.               | NORMAL FLOW.                                 | ACTUAL FLOW<br>IN 1893.                      | EXCESS OR DEFICIENCY.                        |

The next table shows the weekly fluctuations, during 1893, in the flow of the two streams most carefully measured, namely, the Sudbury and the Merrimack. The flow of these streams, particularly the Sudbury, will serve to indicate the condition of other streams in eastern Massachusetts.

In the annual report of the State Board of Health for the year 1890 (pages 338 to 340) a table was printed giving records of the rainfall upon the Sudbury River watershed, and its yield, expressed in inches in depth upon the watershed (inches of rainfall collected), for the sixteen years from 1875 to 1890 inclusive. The corresponding records for the years 1891 and 1892, as taken from the annual reports of the Boston Water Board, were given in the annual report for 1892. In the following table is given the record for 1893, together with the average of the records for the whole nineteen years.

*Rainfall Received and Collected on the Sudbury River Watershed.*

The Sudbury River records are particularly valuable as a basis for estimating the yield of other watersheds in Massachusetts, both on account of the accuracy with which the measurements have been made during the whole nineteen years, and the absence of abnormal conditions which would unfavorably affect the results. It is therefore thought advisable to publish in the following table those portions of the records relating to the yield of this watershed for each of the nineteen years; and in doing so the flow from the watershed is expressed in gallons per day per square mile, instead of inches in depth of rainfall collected, in order to render the table more convenient for use in estimating the probable yield of watersheds used as sources of water supply.

*Yield of the Sudbury River Watershed\* in Gallons Per Day Per Square Mile.*

\* The area of the Sudbury River watershed used in making up these records included water surfaces amounting to about one per cent. of the whole area, from 1875 to 1878 inclusive, and subsequently increasing by the construction of storage reservoirs to about three per cent. in 1886. The watershed also contains extensive areas of swampy land, which, though covered with water at times, are not included in the above percentages of water surfaces.

# ON THE AMOUNT AND CHARACTER OF ORGANIC MATTER IN SOILS AND ITS BEARING ON THE STORAGE OF WATER IN RESERVOIRS.

---

By THOMAS M. DROWN, M. D., Chemist of the Board.

---

Many statements have been made in previous reports of the Board, concerning the injurious effect on impounded water of the organic matter in the bottoms and sides of reservoirs, and great stress has been laid on the importance of removing all vegetation, as well as the upper layers of the soil, before filling a new basin with water.\*

In order to determine in any case just how far it is necessary to go in the removal of the surface soil, a knowledge of the composition of the soil, based on chemical analysis, is a much surer guide than the unaided eye. It is not merely a question of the effective cleaning of the bottom and sides of the reservoir, but also of avoiding the expense involved in stripping the soil to a greater depth than is necessary. In connection with the investigations of the State Board of Health relative to a water supply for the city of Boston and its suburbs, surveys have been made for an immense storage reservoir on the south branch of the Nashua River above Clinton, and it was thought desirable that a thorough knowledge of the character of the soil should be obtained as a basis for determining the amount which it would be necessary to remove to obtain a clean bottom and sides practically free from organic matter. Samples of soils, representing sections of the ground to a depth of three feet, were taken at nine places in Clinton, Sterling, West Boylston, and Boylston, and in one case at the bottom of a mill pond.

Each of these nine sections were divided into six or seven samples for analysis, the upper portion being divided into thin layers of two to three inches, the lower portions, with less organic matter, into layers of six inches to one foot in depth.

---

\* Compare special report upon the examination of water supplies, 1890, pages 748, 772, 773; report for 1891, page 381.

The amount of organic matter in these samples was determined (after careful drying to a constant weight at 100° C.) by heating the samples to a bright red heat. The loss on ignition thus obtained represents approximately the organic matter in the samples. But in order to get a better knowledge of the character of this organic matter, the amounts of carbon and of nitrogen were also determined in each sample — the former by combustion in oxygen, the latter by the Kjeldahl method. In series 9 and 10, the amount of hydrogen was also determined.\*

Owing to the heterogeneous character of many of the samples, composed often of a mixture of soil, roots and large stones, it is sometimes extremely difficult to get a sample for analysis that shall fairly represent the layer in question. Perhaps some of the apparent irregularities in the results may be due to this cause. But though this difficulty is inherent in the investigation it is not believed to seriously affect the results, or the conclusions drawn from them.

The results obtained in the analyses of the nine sections of soil, and the deposit from the bottom of the mill pond, are given in the accompanying tables. The largest amount of organic matter found was from a swamp at the head of Boylston Mill Pond (Series 7), and the next largest in amount from the hillside near the site of the proposed dam (Series 4). The other series, from very dissimilar ground, did not differ very widely in the amount of organic matter present, although they included both unwooded and uncultivated land and wooded and manured pasture land. But in all the series there is usually a rapid falling off in the amount of the organic matter below a depth of nine to eleven inches. At the depth of three feet the amount of organic matter, as shown by the loss on ignition, in no case reaches two per cent., and in the majority of the cases it is below one per cent. The mud taken from the bottom of the Mill Pond at different points contained very variable amounts of organic matter, from almost nothing at one place in the shallow portion to nearly 15 per cent. in the deeper portion.

It was thought that the relation of the amount of nitrogen to the amount of carbon in the organic matter might throw some light on its character and its likelihood to undergo decomposition. This relation is given to the column headed  $\frac{C}{N}$ . The only series in which the nitrogen ratio is noticeably higher than the rest is No. 5, from

---

\* All the analyses in this investigation were made by Miss Elizabeth Mason.

low pasture land. Series Nos. 4 and 6, both from hillsides, show a noticeably high carbon ratio, and the others are not very dissimilar in their proportion of carbon to nitrogen.

An attempt was made to imitate the conditions which would obtain if the reservoir should be filled with water without removing the soil, in order to determine what would be the effect of each of the soils examined on water in contact with it. It is obvious that no laboratory experiment could exactly reproduce the conditions which would exist in a reservoir. Thus it would not be easy to imitate the period of long stagnation of the water during the summer, when the deeper layers of the water are in contact with the soil, without an opportunity to get a fresh supply of oxygen from the air. Still it was thought that some idea of the effect of the different soils on the water could be obtained by treating the samples with water for a definite time, and then examining the solutions thus obtained with respect to the character of the organic matter dissolved. In order to hasten the action of the water on the soils, it was heated to 65° C., and the time of contact at this temperature was six hours. The waters were then filtered and the filtrate examined by the usual methods used in the sanitary analysis of water. After standing one week the waters were again tested for free ammonia, to ascertain the amount of decomposition which had gone on in this time, thus obtaining information as to the character of the organic matter dissolved. The *actual amounts* of organic matter found in these solutions, as indicated by the albuminoid ammonia and oxygen consumed, are not especially significant, since they would probably have been very different if another temperature or a greater or less time of treatment had been adopted. But a comparison of the amounts dissolved from the soils in each series, and a comparison of the series with each other, yield information as to the relative facility with which each of the samples examined give up organic matter to water with which it comes in contact.

In the various experiments tried the proportion of soil to water differed, and in some cases distilled water was used and in others Cochituate water. But in the tables the results of series 1 to 8 have been calculated to represent the effect of the treatment of 100 grams of soil with two litres of pure water at 65° C. for six hours. In series 9 and 10 no heat was employed. In these experiments 250 grams of each sample were placed in a bottle with two litres of pure distilled water. After one week, one litre of this water was filtered

off and analyzed, and at the end of the second week the remaining water was examined.

In comparing these tables of analyses of the waters with the corresponding tables giving the percentage determinations of loss on ignition, carbon and nitrogen, a general agreement will be noticed; that is to say, the samples containing the most organic matter give, as a rule, the most concentrated solutions of organic matter. But the analyses do not indicate more than a very general correspondence of this kind. It will also be noted that the amount of decomposition going on in these solutions, indicated by the increase of free ammonia on standing one week, is, in general, also proportional to the amount of organic matter present. The most notable increase in the free ammonia is generally in the solutions prepared from the surface samples. In solutions from the deeper samples there is generally a decrease of free ammonia indicating doubtless its oxidation to nitrates. The samples from the bottom of the Mill Pond (series 8) give solutions which have little or no tendency to develop free ammonia. This might be expected from the fact that the organic matter they contain has long been in contact with water.

The effect of the soil on the color of water is given both for colorless distilled water, and for Cochituate water having an original color of about 0.55 on the scale used in the analyses of the State Board of Health. In these color determinations the water was not heated, and the length of time of contact with the soil was about 18 hours. It will be noticed that in some cases the deeper samples actually diminished the color of the Cochituate water.

As a preliminary conclusion, based on the facts determined in this investigation, it may be said that the effect of the organic matter in these various soils on the water in contact with them is simply a question of its amount, and that its origin and composition seem to be without marked influence. The watershed from which the samples were taken is very sparsely populated, and the organic matter in all cases is mainly of vegetable origin.

It is probable, therefore, that we need only concern ourselves with the amount of organic matter in a soil of this character in determining the necessity of its removal, and as a provisional standard we may perhaps fix 1.5 to 2 per cent. of organic matter, as determined by the loss on ignition of the sample dried at 100° C., as the permissible limit of organic matter that may be allowed to remain on the bottom and sides of a reservoir.

## SERIES 1.

*From a Cornfield One-quarter Mile below Clarendon Mills, West Boylston. Cultivated Fertilized Ground in Bottoms. Samples taken from Surface to Three Feet below Surface. All Samples dried at 100°C.*

## EXPERIMENTS UPON THE PURIFICATION OF SEWAGE AND WATER AT THE LAWRENCE EXPERIMENT STATION.\*

---

By GEORGE W. FULLER, Biologist in Charge.

---

The year 1893 is the sixth that the experimental work of the Lawrence Experiment Station has been continued. The work is carried on under the general supervision of Hiram F. Mills, A.M., C.E., a member of the State Board of Health. Mr. Allen Hazen, chemist, was in direct charge of the station until March 1, 1893, when he was given a leave of absence and accepted the position of chemist to the Department of Water Supply and Sewerage of the World's Columbian Exposition. The writer, who had previously been in charge of the biological department, succeeded Mr. Hazen in charge of the station. Mr. Harry W. Clark is chemist, and Mr. F. L. Fales has compiled the records and prepared the tables showing the results of the work. Messrs. W. R. Copeland and Louis Weinberg are assistant biologists and Mr. F. B. Forbes is assistant chemist. Professors T. M. Drown and W. T. Sedgwick of the Massachusetts Institute of Technology are, respectively, consulting chemist and biologist, having a general oversight of the chemical and biological investigations.

The year has been an important one in the history of the experimental sewage filters, in that the results of earlier investigations have been confirmed and additional knowledge has been obtained as to the management necessary to maintain the continuous efficiency of such filters.

The process of purification of sewage by intermittent filtration consists of intermingling the sewage in the pores of the filtering material with sufficient air, for a sufficient time, in the presence of micro-organisms which quickly establish themselves there.

---

\* A full account of the work done at the Lawrence Experiment Station for the years 1888 and 1889 is contained in a Special Report of the State Board of Health upon the Purification of Sewage and Water, 1890. A similar account for the years 1890 and 1891 is contained in the Twenty-third Annual Report of the Board for the year 1891, and for the year 1892 in the Twenty-fourth Annual Report of the Board for that year.

Sewage filters resemble complex living organisms, in that ventilation and respiration must be maintained, otherwise their functions are interrupted and their lives as filters come to an end.

When sewage passes through a filter a portion of the insoluble matter or sludge is deposited upon or near the surface. The result, eventually, unless preventive measures are adopted, is a clogging at the surface, which, owing to interrupted ventilation, causes a deterioration in the quality of the effluent, and subsequently, owing to the increased capillary attraction and frictional resistance to the passage of sewage, a reduction in the quantitative efficiency of the filter. The amount of sludge in sewage varies, but, unless care is taken, any sewage will in time clog any ordinary filter. In the Annual Report of the Board for 1892 it was stated that when other conditions are the same, the clogging is proportional to the sludge carried in the applied sewage. It is of importance therefore to consider not only the filtering materials but also the applied sewage in order to learn its average strength and the limits in strength between which it varies.

#### CHARACTER OF THE SEWAGE.

The sewage used at the Experiment Station is pumped through a two and one-half inch pipe, 4,300 feet long, from a sewer which drains the streets, houses and stores of the most densely populated sections of the city of Lawrence.

#### *Samples of Sewage for Analysis.*

Samples of sewage have been regularly collected for analysis as follows : —

1. *Regular Sewage.* On at least four days in a week a gallon bottle has been filled from a large tank of sewage. While the sample was intended to be as far as possible a representative one, it necessarily represented accurately only a small fraction of the total amount of sewage used ; and there is also considerable difficulty in mixing several hundred gallons of sewage so as to get a sample with its proper share of suspended matter.

2. *Average Sewage.* On one day each week (Tuesday), a sample has been taken by collecting directly from the pump (without allowing any opportunity for sedimentation), quantities of sewage propor-

tional to the amount of each lot of sewage pumped during the day. The average results from numerous samples collected in this manner give satisfactorily the average composition of all sewage applied to the filters.

3. *Sewage for Filters Nos. 1, 6 and 9A.* In order to learn the variations in strength of sewage at different times of the day and to obtain more accurate data upon the storage of organic matter in the filters there have been collected weekly three mixed samples representing each dose applied during the week to Filters Nos. 1, 6 and 9A, respectively. In order to keep the samples for one week without putrefaction and decomposition, a small amount of mercuric acetate was placed in the bottle.

*Monthly Averages of Analyses of Regular Sewage Samples.*

\* In all of the Lawrence analyses the oxygen consumed has been determined after boiling two minutes.

The above analyses represent four samples each week taken from one of the sewage tanks, usually in the morning, and the results are directly comparable with the analyses published for previous years.

With regard to the comparison of the results with each other it is to be mentioned that the sewage for Filter No. 1 was all pumped late in the afternoon during the cold months, December to April, inclusive; in May and June it was pumped early in the morning, and during the rest of the year part in the early morning and the

remainder in the afternoon. Sewage for Filter No. 6 was regularly pumped in the middle of the day. In the case of Filter No. 9 A the sewage was pumped late in the afternoon during the cold months, December to April, inclusive, and early in the morning during the remainder of the year. The results are comparable with corresponding results obtained in 1892.

\* The sewage was not treated in this manner January 1 to 20; the results for this month given in the table represent the analyses of January 21 to 31.

The above analyses represent the supernatant liquid after the sewage represented by the regular samples had been treated with alum, in the proportion of 1,000 pounds of alum to 1,000,000 gallons of sewage, and allowed to settle for four hours. These results show that 52.4 per cent. of the total albuminoid ammonia and 84.3 per cent. of the bacteria were removed. The high numbers of bacteria in June and July appeared to be due to a growth of bacteria on the sides of the barrels where some organic matter had accumulated. The removal of this organic matter from time to time caused the number of bacteria in the supernatant liquid to become normal.

*Monthly Averages of Supernatant Liquid from Settled Sewage for Filter No. 13 A.*

[Parts per 100,000.]

| MONTH — 1893.       | Free Ammonia. | ALBUMINOID AMMONIA. |          |            | Chlorine. | Oxygen Consumed. | Bacteria per Cubic Centimeter. |
|---------------------|---------------|---------------------|----------|------------|-----------|------------------|--------------------------------|
|                     |               | Total.              | Soluble. | Insoluble. |           |                  |                                |
| October, . . . . .  | 2.70          | .43                 | .25      | .18        | 6.22      | 2.32             | 844,000                        |
| November, . . . . . | 3.13          | .60                 | .32      | .28        | 18.73     | 3.64             | 898,000                        |
| December, . . . . . | 3.25          | .60                 | .30      | .30        | 5.98      | 3.12             | 856,000                        |
| Averages, . . . . . | 3.08          | .64                 | .29      | .25        | 10.31     | 2.99             | 866,000                        |

The analyses above represent the supernatant liquid after the sewage represented by the regular sample had been allowed to settle for four hours. These results, when compared with those of the regular samples of sewage, taken on the same days, show a removal of 18.2 per cent. of the total albuminoid ammonia and 12 0 per cent. of the bacteria by sedimentation.

*Comparison of the Strength of the Sewage.*

Bringing together for comparison the average results of the several series of sewage samples, we have : —

[Parts per 100,000.]

|                              | Free Ammonia. | ALBUMINOID AMMONIA. |          |            | Chlorine. | Oxygen Consumed. |

\* Estimated as equal to that in the regular sample.

It will be seen that the average sewage for the day was the most concentrated, although only a little stronger than the sewage applied to Filters Nos. 1, 6 and 9A. The regular sewage was the most dilute of all, as was the case in 1892.

Investigations are under way to show the relation of the strength of the sewage as drawn at the Experiment Station to that of the original sewage in the Lawrence Street sewer. The results of two such series of analyses are given in the table below. On January 16 and 17, 1894, when the first series was collected, the weather was

clear and cold, and probably very little surface water entered the sewer. The second series was taken during a storm. The amount of precipitation (rain and melted snow) was 1.47 inches, the greater part of which was snow; considerable rain fell during the night of January 30, however, and found its way to the sewer. In the second series estimates of the quantity of sewage flowing in the sewer were made from observations of the depth of sewage in the sewer.

*Results of Analyses of Hourly Samples of Sewage from the Lawrence Street Sewer.*

From the data obtained in the second series there was calculated a representative analysis of all the sewage which passed through the sewer during this period of twenty-four hours. In the following table this representative analysis of all the sewage flowing for twenty-four hours in the sewer is compared with the average analysis of all the sewage pumped at the Experiment Station during this period (7 A.M. to 5 P.M. January 31).

[Parts per 100,000.]

| JANUARY 30 AND 31, 1894.     | Free Ammonia. | ALBUMINOID AMMONIA. |          |            | Chlorine. | Oxygen Consumed. |
|------------------------------|---------------|---------------------|----------|------------|-----------|------------------|
|                              |               | Total.              | Soluble. | Insoluble. |           |                  |
| Lawrence Street sewer, . . . | 1.40          | .54                 | .36      | .18        | 5.56      | 2.87             |
| Experiment station, . . .    | 2.70          | .73                 | .49      | .24        | 5.72      | 5.50             |

These results indicate that the average sewage applied to the experimental filters during this period was considerably stronger than the average original sewage flowing in the sewer. Whether or not the difference is always so marked will require further experiments to determine. It is instructive to compare the analyses of the sewage in the two series, and also the variations at different times during the day in each series.

It has been found that the sewage in the Lawrence Street sewer contains considerable dissolved oxygen, while the sewage as pumped at the Station contains none. Experiments are in progress to compare the results of purification by filtration of fresh sewage from the Lawrence Street sewer and of sewage as pumped at the Station, both with and without aeration.

Since clogging and consequent interference with ventilation are the chief factors to be considered in studying the continuous efficiency of filters, it is of importance to know the strength of the sewage which has been treated and the amount of sludge which it contained. In the table below are given averages of analyses for the year 1893 of the sewage applied to the experimental filters at Lawrence, and of that of the cities and towns in Massachusetts which purify their sewage by intermittent filtration.

*Average of Analyses of the Sewage applied to the Experimental Filters at Lawrence, and of that applied to the Filters used by certain Cities and Towns.*

[Parts per 100,000.]

| SEWAGE.                 | Free Ammonia. | ALBUMINOID AMMONIA. |          |            | Chlorine. | Oxygen Consumed. |
|-------------------------|---------------|---------------------|----------|------------|-----------|------------------|
|                         |               | Total.              | Soluble. | Insoluble. |           |                  |
| Lawrence, . . . . .     | 3.07          | .74                 | .38      | .36        | 7.15      | 3.63             |
| Framingham, . . . . .   | 1.88          | .38                 | .19      | .19        | 4.93      | 5.14             |
| Marlborough, . . . . .  | 2.08          | .62                 | .38      | .24        | 7.85      | 6.29             |
| Gardner, . . . . .      | 1.80          | .45                 | .21      | .24        | 8.11      | 3.94             |
| Westborough,* . . . . . | 1.07          | .19                 | .05      | .14        | 2.27      | 2.72             |

\* Two samples from Westborough were analyzed; the other results (except Lawrence) are averages of semi-monthly analyses.

This table shows that the sewage applied to the experimental filters contains more sludge than the sewage of the other places, and consequently the experimental filters require more attention to prevent clogging than do the several large filters in actual service which receive more dilute sewage.

#### AVERAGE PURIFICATION OF SEWAGE BY THE SEVERAL FILTERS IN 1893.

In the table below are given the average percentages of removal of organic matter (albuminoid ammonia) and of bacteria by the several filters to which ordinary sewage was applied. For the construction and details of operation and results see pages 429-452.

*Average Per Cent. of Albuminoid Ammonia and of Bacteria removed from Sewage by the Several Filters, with Average Rates of Filtration, 1893.*

| NUMBER OF FILTER. | Average Rate of Filtration. (Gallons per Acre Daily for six Days in a Week.) | Per Cent. of Albuminoid Ammonia Removed. | Per Cent. of Bacteria Removed. | NUMBER OF FILTER. | Average Rate of Filtration. (Gallons per Acre Daily for six Days in a Week.) | Per Cent. of Albuminoid Ammonia Removed. | Per Cent. of Bacteria Removed. |
|-------------------|------------------------------------------------------------------------------|------------------------------------------|--------------------------------|-------------------|------------------------------------------------------------------------------|------------------------------------------|--------------------------------|

These results show that with most of the filters the removal of organic matter was over 90 per cent., while five of them removed 95 per cent. or more. It is to be stated, however, that both the quantitative and qualitative efficiency were in many cases below the normal during the early part of the year. This was owing to the fact that for some time previous the filters had been operated in a manner believed to be unlikely to produce the best results, but tried for the sake of learning the effect of certain methods of operation. The methods of treatment by which the filters resumed their former ability to purify sewage are described and discussed on pages 412-421.

#### PERMANENCY OF SEWAGE FILTERS.

In studying the subject of purification of sewage by filtration a matter of vital importance is the question of the permanency of filters. It is well known that with filters of suitable material sewage may be purified at a rate of more than 100,000 gallons per acre daily, with a removal of over 90 per cent. of the organic matter. It is also known that some of the organic matter of the sewage is stored at and near the surface of the filter, and that under some circumstances there is a certain amount of storage for some distance below the surface. It has been learned that in the case of filters which have regularly filtered sewage at a comparatively high rate it is eventually necessary to spade up the surface in a manner corresponding to ploughing, and later to remove the clogged surface layers and replace them with fresh material. We shall consider the treatment of the upper layers of a sewage filter, say the upper six inches, under the heading of management of filters necessary for their successful operation, and regard the permanency of the filters as the ability of the main body of the sand, below the upper six inches, under proper treatment, to purify sewage for an indefinite time.

In the Annual Report for 1891 it was shown that the storage of organic matter in the filters at that time was steadily increasing. This conclusion was drawn from repeated determinations of nitrogen stored in the sand. During the past two years numerous examinations have been made, but, owing to the unequal distribution of sewage through the material caused by trenching and in other ways, it was found to be practically impossible to obtain results which represent correctly the entire filter. Accordingly the calculations of the quantities of organic matter stored within the filter have been made after another method in 1893. The results of repeated determinations of

nitrogen stored in the sand during the earlier years of the experiments indicated that 30 per cent. of the applied nitrogen was not to be found either in the sand or in the effluent. It probably disappeared in the atmosphere; possibly as nitrogen gas. To the nitrogen found in the average analyses of representative samples of each effluent has been added 30 per cent. of the amount in each case, and the difference between this corrected quantity in the effluent and the quantity of nitrogen in the applied sewage has been taken to represent the amount of nitrogen stored in the filters. In the table below are given the percentages which the nitrogen in the effluents, calculated as described above from the averages of representative analyses, formed of the nitrogen in the applied sewage, by months. The sign minus, of course, indicates a removal of stored nitrogen.

*Per Cent. of Applied Nitrogen that was stored in the Sewage Filters, in 1893.*

*Summary and Conclusions.*

1. It will be seen that the only filters in which there was a continued storage of nitrogen were Nos. 4, 15 B and 16 B. These filters represent the extreme limits in the size of materials and the results are explained by the fact that there was an insufficient amount of air for the complete oxidation and nitrification of the applied sewage. From this it follows that the permanency of sewage filters is independent of the size of material, but is directly dependent upon the treatment which they receive.

2. The removal of large amounts of stored organic matter in the spring and early summer months, under favorable conditions, is one of the most marked characteristics of sewage purification by intermittent filtration.

3. It will be noticed that in several cases the storage of nitrogen during the winter months was very slight, while in some instances there was a removal. This is not apparent from the degree of purification of the corresponding effluents, in which the free ammonia was very high, and this seeming discrepancy is explained by the fact that while freezing winter weather interferes with nitrification it does not seriously affect the oxidation of carbonaceous matter to free ammonia.

4. The average results from all the filters, some of which have been in operation regularly for six years, indicate that there was practically no more nitrogen stored in the filters at the end than at the beginning of the year. From this it appears that, with the main body of the sand the same, sewage filters may continue to purify sewage for an indefinite time provided they receive proper treatment to insure sufficient ventilation for the oxidation and nitrification of the applied sewage.

**MANAGEMENT OF FILTERS TO SECURE CONTINUOUS EFFICIENCY.**

An outline of the results obtained by different methods for the conservation of the efficiency of sewage filters is as follows :—

*Systematic Raking followed by Scraping.*

In 1890 it was learned that the interruption of the ventilation of a filter, owing to clogging by the stored organic matter of the sludge at the surface, was prevented, to a great extent, by a systematic weekly raking to a depth of about one inch. Eventually the storage

of sludge in the material disturbed by the weekly raking is so great that ventilation is no longer afforded by this means. It is then necessary, in order to insure the continued efficiency of the filter, to present cleaner material at the surface; and one of the ways by which this may be accomplished is by removing the clogged material by scraping and replacing it with fresh material. (See page 420 with regard to the addition of new material.)

*Filter No. 1.* — This filter is one two-hundredths of an acre in area and contains 63 inches in depth of sand of an effective size\* of 0.48 millimeter. On June 2, 1892, there were removed from the surface 5 inches of clogged material which had been more or less disturbed and mixed together by trenching. This was four years and five months after the filter was first put in operation. No new material was added at this time. The efficiency of the filter was satisfactory during the following months until freezing weather set in. The quality of the effluent improved during March and April, but the surface soon became clogged so that the sewage failed to disappear from the surface in twenty-four hours. On May 5, 1893, a layer of clogged sand, 4 inches in depth, was removed by scraping and new material added to restore the filter to its original depth of 63 inches. The total depth removed in the five years and four months up to this date was 9 inches, or 7.9 cubic yards per million gallons of sewage filtered. The 4-inch layer removed May 5, 1893, was equivalent to 15 cubic yards per million gallons filtered since June 2, 1892. Very good results followed this treatment. The rate of filtration up to July 10 was 120,000 gallons per acre daily for six days in a week; July 11 to August 31, 60,000 gallons; September 1 to 17, 80,000 gallons; September 18 to December 22, 120,000 gallons; and December 23 to 31, 60,000 gallons. During the six months, May to October, inclusive, the average removal of organic matter (albuminoid ammonia) and bacteria from the applied sewage was 93.2 and 95.5 per cent., respectively, while the nitrification was very high. The averages of the analyses of the effluent showed that it contained 3.16 parts per 100,000 of nitrogen as nitrates, which indicates a removal of some of the organic matter stored in the sand.

*Filter No. 6.* — This filter contains 44 inches in depth of mixed coarse and fine sand of an effective size of 0.35 millimeter. The surface has been raked regularly once a week since Jan. 1, 1891.

---

\* The "effective size" means that ten per cent. by weight of the sand grains are finer than the diameter given.

On March 29, 1892, 2 inches of clogged material were scraped from the surface and replaced with new material. The filter was spaded over in layers to a depth of 2 feet on May 19, 1892, to break up stratification. The surface became clogged again Sept. 25, 1893, when 2 inches were again scraped off. The total depth of 4 inches removed up to this date is equivalent to 5.8 cubic yards of sand per million gallons of sewage filtered; the 2 inches removed Sept. 25, 1893, are equivalent to 9.7 cubic yards per million gallons filtered since May 19, 1892. During this latter period the average removal of organic matter (albuminoid ammonia) and bacteria from the applied sewage was 94.2 and 99.3 per cent., respectively. The effluent contained, on an average, 2.83 parts per 100,000 of nitrogen as nitrates. The average rate of filtration was 62,400 gallons per acre daily for six days in a week. From September 1 to December 21 the rate was 90,000 gallons, and from December 22 to 31, 50,000 gallons.

*Systematic Scraping when Necessary, without Raking.*

*Filter No. 9 A.* — This filter is 60 inches in depth and contains sand of an effective size of 0.17 millimeter. The upper 6 inches were removed, and the rest of the material taken out and replaced dry May 20, 1892, in order to break up stratification. The surface was raked weekly until July 20, 1892, but since that time it has not been raked, but was scraped whenever the surface became sufficiently clogged to prevent the passage of sewage through the filter. The filter was scraped eleven times from May 20, 1892, to Nov. 16, 1893, and on the latter date the applied sewage failed to disappear just after scraping, indicating a clogging beneath the surface. The filter was restored to its original depth by the addition of new material after scraping on March 14 and Sept. 25, 1893. The total depth removed was 5.54 inches, which is equivalent to 13.8 cubic yards per million gallons of sewage filtered during the period. The rate of filtration, 120,000 gallons per acre daily, for six days in a week, is very high for this material. The average removal of organic matter (albuminoid ammonia) and bacteria from the sewage for the entire period was 94.1 and 98.3 per cent. respectively. The nitrogen as nitrates averaged 2.03 parts per 100,000 in the effluent.

A decided objection to this method of treatment is that the frequent interruption in ventilation causes a temporary decrease in nitrification and an increase in the storage of organic matter. With

long intervals between scrapings this would not be serious; but, as in the case of Filter No. 9 A, there may eventually come a time when the scrapings are so frequent that nitrification does not get fully re-established before clogging occurs again.

It was necessary to scrape, after November 16,  $4\frac{1}{2}$  inches, before the sewage would disappear readily. As the removed sand did not contain sufficient stored organic matter to explain this clogging, its final interpretation must be postponed until something is known of its subsequent history. It is to be mentioned, however, that compactness of the material seemed to be an important feature.

*Systematic Scraping at Regular Intervals, without Raking.*

No experiments upon this point have been made as yet at the Experiment Station, but the sewage filters at Gardner have been treated in this manner for more than two years. The sand in these filters has an effective size of 0.10 to 0.24 millimeter, and the sewage is applied with a two-day interval of rest at an average rate of about 60,000 gallons per acre daily. About one-eighth inch of scum and clogged sand is removed once in ten days to two weeks. After scraping off the stored sludge the sand is raked to a depth of 1 to  $1\frac{1}{2}$  inches to loosen the material. This treatment appears to be very satisfactory.

*Systematic Raking followed by Ploughing.*

Upon the application of sewage to filters of coarse sand the sludge passes deeper into the material than in the case of filters of fine sand; eventually a clogging occurs at a point just beneath that reached in the weekly raking (1 inch deep). Under these circumstances the surfaces have been spaded over in a manner corresponding to ploughing.

*Filter No. 3 A.*—This filter contains 30 inches in depth of coarse sand above 30 inches of fine sand. The effective sizes are 0.48 and 0.08 millimeter, respectively. The surface was spaded over 6 inches deep Oct. 19, 1892, and, with the aid of weekly raking, the applied sewage disappeared promptly until August, 1893, when the filter became clogged again. The surface was spaded over 6 inches deep August 14, after which the applied dose of sewage, equivalent to 60,000 gallons per acre daily for six days in a week, disappeared promptly, and the quality of the effluent steadily improved up to September 1, when the experiment was discontinued.

*Filter No. 5 A.*—This filter contains 63 inches in depth of screened gravel of an effective size of 1.40 millimeters. Clogging beneath the surface became apparent June 12, 1893, and was relieved by raking 2 inches deep. The rate of filtration was 120,000 gallons per acre daily for six days in a week. Sub-surface clogging appeared again September 15, when the surface was spaded over 6 inches deep. On October 30 the rate was increased to 160,000 gallons per acre, and clogging began to appear again the first of December.

Under this method of treatment it would be necessary, if a high rate of filtration were maintained, to resort eventually to scraping, as was the case with Filter No. 5 A in December.

### *Trenching.*

*Filter No. 2.*—This filter contains 60 inches in depth of very fine sand of an effective size of 0.08 millimeter. In the winter of 1892-93 the surface of the filter became very badly clogged, and on March 2 there were dug two circular trenches, each one foot wide and two feet deep, one and a half and five feet, respectively, from the edge of the filter. These trenches were filled to within three inches of the top with sand of an effective size of 0.19 millimeter. The prescribed dose of 40,000 gallons per acre daily for six days in a week was then taken without difficulty and the quality of the effluent steadily improved. On September 1 the dose was increased to 60,000 gallons. During October the trenches gradually showed the effect of clogging, and finally were unable to take the prescribed dose. At the same time the free ammonia in the effluent began to increase. On October 30 the upper two inches of sand in the trenches were removed and replaced with fresh material. This afforded but little relief, owing to a clogging further down in the filter, as is explained beyond. The sand removed was equivalent to 7.9 cubic yards per million gallons of sewage filtered since March 2, 1893, and contained 118 parts per 100,000 of albuminoid ammonia. The average removal of organic matter (albuminoid ammonia) and bacteria from the applied sewage during this time was 95.7 and 99.7 per cent., respectively. The effluent contained on an average 2.86 parts per 100,000 of nitrogen as nitrates, which indicates a removal of some of the organic matter stored in the sand during the winter months. The average rate of filtration was 43,000 gallons per acre daily for six days in a week.

The trenches in this filter probably doubled the quantity of sewage which could be successfully treated, and moreover caused a marked improvement in the quality of the effluent.

### *Construction of Trenches.*

When coarse sand is placed in trenches dug in finer sand some of the sludge of the applied sewage in time works down to the fine sand at the junction, where the gradually increasing storage causes an increase in the capillary attraction, and eventually so large a proportion of the space between the sand grains is constantly filled with water that the ventilation is seriously impaired and the frictional resistance is so great that both the qualitative and quantitative efficiency of the filter are crippled.

Filter No. 2 became clogged in this manner, and on Dec. 2, 1893, the coarse sand was removed from the trenches and also two and a half inches of the fine sand beneath it. After raking the sides and the bottom of the trenches, a layer five inches in depth of thoroughly mixed coarse and fine sand, with the coarse gradually decreasing downward, was put back, with a view to preventing the occurrence of any sharply dividing line in the difference in capillary attraction. As far as can be judged at the time of writing the effect upon the filter was very beneficial. In the case of deep trenches, where much of the sewage passes through the sides, it would probably be desirable to treat the sides in a somewhat similar manner.

Some experiments have been made, showing comparisons of the capillarity and other physical characteristics of coarse and fine sand and several mixtures of the two. The materials (Nos. 1 and 2 sands) were dried and thoroughly mixed. In the table below are given the mechanical composition, effective size, uniformity coefficient, per cent. of open space and specific gravity, as well as the capillarity in each case. The capillarity was determined by finding the amount of water held in the pores of the sand after draining twenty-four hours, and it is instructive to note that the mixtures of one part coarse and three parts fine and equal parts of coarse and fine held more water than the fine alone, while the other mixture held only a little less.

*Resting.*

*Filter No. 4.* — This filter contains 60 inches in depth of fine river silt of an effective size of 0.04 millimeter and has received sewage since June 24, 1889, in a trench of coarse mortar sand. This trench covers one-third the area of the filter, is 14 inches deep, and is filled to within 3 inches of the top with the coarse sand. In the winter of 1892–93 the trench became clogged and unable to take the dose of 40,000 gallons per acre daily for six days in a week. On March 6 the upper 2 inches of sand in the trench, containing 75 parts per 100,000 of albuminoid ammonia, were removed. This was a total removal of  $3\frac{1}{2}$  inches since June 24, 1889, and equivalent to 3.79 cubic yards per million gallons; the 2 inches removed March 6, 1893, were equivalent to 9.3 cubic yards per million gallons filtered since May 9, 1892, the date of the first removal. This did not afford relief, and the coarse sand was taken out of the trench, the upper half inch of the fine sand beneath it was removed and the coarse sand replaced. Clogging again occurred in May, and a new trench was constructed June 2, the old one being allowed to rest. Analyses of the sand showed that there was a reduction of 39 per cent., from June 2 to August 16, of the albuminoid ammonia stored in the trench. Another analysis on October 30 showed no farther reduction, but the sewage was applied to the original trench from that date throughout the year without difficulty. The rate of filtration since June 2 has been 30,000 gallons per acre daily for six days in a week. The average removal of organic matter (albuminoid ammonia) and bacteria from the applied sewage, May, 1892, to October, 1893, inclusive, was 92.9 and 99.993 per cent., respectively. For November and December, 1893, these figures became 98.2 and 99.999, respectively. The nitrogen as nitrates in the effluent averaged 1.09 and 2.14 parts per 100,000, respectively, during the two periods.

The construction of double trenches, allowing each to work and rest alternately, in periods, is of much practical value; and, moreover, the removal of stored organic matter by simple resting indicates that this inexpensive method is worthy of careful consideration in the treatment of large areas of clogged filtering material.

### *Addition of New Material.*

For some time it has been known that the passage of sewage through sand increases the amount of stored organic matter, which forms a sticky coating around the sand grains and thereby increases the capillary attraction. Accordingly, when new material with grains of the same size and original composition is put upon old material to take the place of clogged material removed by scraping the effect is similar to placing coarse sand above fine, and the result is a clogging at the junction. This was found to be the case in Filters Nos. 1 and 6, which indicated furthermore that the finer the material and the nearer the junction was to the surface the quicker the clogging became manifested. To remedy this the filters were spaded over, the old and new material mixed together, so as to break up the layer at the dividing line between the materials of unlike capillary attraction, and satisfactory results followed.

### *The Management of Sewage Filters with Regard to Winter Weather.*

The purification of sewage by intermittent filtration is ordinarily attended with more difficulties during the freezing winter weather than during the remainder of the year, owing to an apparent diminution in the activity of the micro-organisms in the presence of frost; to the less favorable conditions for ventilation because freezing interferes with draining, and the pores of the sand are more or less filled with frost; and to the danger of the sewage freezing to the sand before it disappears, whereby further filtration is impossible until a thaw comes. It is therefore of the utmost importance that the treatment of the filters be such that the conditions for operation be as favorable as possible during the winter.

Most of the experimental filters received their preparation for the winter on December 2, and on the following day severe winter weather began. The filters showed great improvement in the readiness with which they took the applied sewage, but the improvement in the quality of the effluent was far less than would have been the case in warmer weather. This indicates that the filters should be prepared for the winter sufficiently early to be in their best condition in every way when freezing weather begins. It does not appear to be advisable to postpone this treatment in Massachusetts after the 1st of November.

In regard to the preparation necessary, it may be stated that the

clogging should be removed as far as practicable, and in a majority of cases the surface can with great advantage be arranged in alternate ridges and trenches. The ordinary winter sewage is sufficiently warm to melt some of the snow in the trenches, but in so doing becomes so chilled that in many cases a sheet of ice is formed beneath the unmelted snow and above the sand in the trench. The sewage will slowly pass into the sand and form in this way a very inexpensive and effective winter cover. It is also to be mentioned that at Framingham the filters, which were planted with corn (maize), were afforded such covers by allowing the snow and ice to rest upon the corn hills.

Owing to the limited area of the experimental filters there is but little opportunity for lateral filtration (a very important feature in large filters), and it is not practicable to ridge and trench the surface of most of the Lawrence filters because the sewage would pass through in places too quickly. It appears that large filters in actual practice are much less difficult to operate in winter weather than the experimental filters.

### *Summary and Conclusions.*

The several methods of managing filters, with particular reference to the removal of clogging in the surface layers, which have been applied, with varying results, may be summarized as follows:—

1. Systematic raking, with occasional harrowing or ploughing, is very satisfactory, particularly for coarse materials.

2. Systematic scraping at regular intervals (followed by raking to loosen the material) gives very good results, especially for fine materials.

3. Systematic scraping when necessary, without raking or harrowing, is not advisable.

4. The efficiency of very fine material (clogged or not clogged) is much increased by trenching with coarse material.

5. Such trenches should contain carefully graded materials at the bottom to prevent clogging at the junction of the coarse and fine sand.

6. When new material is put on to old to replace clogged material removed by scraping, it is always advisable to mix the old and the new together in order to prevent clogging at the junction of layers of unlike capillary attraction.

7. The removal of stored organic matter by resting for a limited

period is sufficiently great to render this simple and inexpensive method worthy of careful consideration in cases of clogging where the available area is not too limited. It may be mentioned here that the depth of material necessary to be removed from the surface of several of the experimental filters would doubtless have been considerably less if they had been allowed to rest for a short time.

8. It is important that the treatment of filters be such that the conditions of operation be as favorable as possible during the cold winter weather.

9. Great care should be taken, especially in the case of filters of fine material, that the capacity of the filter be not taxed during the winter months to such an extent that more organic matter is stored throughout the sand than can be removed during the spring and early summer, which is the period of highest nitrification.

#### EXPERIMENTS UPON THE RAPID FILTRATION OF SEWAGE FROM WHICH THE SLUDGE HAS BEEN REMOVED BY DIFFERENT METHODS.

The question of clogging has been considered in the preceding pages with regard to the removal of sludge after its application to and partial storage in the sand. Another aid to prevention and relief is the removal of as much of the sludge as possible before the application of the sewage to the filter. This may be done by different treatments as follows:—

I. By rapid filtration through coarse gravel, with the aid of a current of air drawn through the gravel.

II. By chemical precipitation.

III. By sedimentation.

IV. By mechanical devices, such as very fine screens or wire cloth. (Results as yet incomplete.)

After treating sewage by one of the first three of these different methods it has been in each case applied to a filter of sand 5 feet deep, having an effective size of grain of 0.17 to 0.19 millimeter.

#### *I. (Filters Nos. 12 A, 15 B and 16 B.)*

*Filters Nos. 15 B and 16 B* are each 65 inches in depth and contain gravel stones of an effective size of 5.10 millimeters. They were put in operation July 25, 1892. A current of air has been drawn through No. 15 B, by means of an aspirator attached to the tank near the bottom, since March 18, 1893, and through No. 16 B since Jan. 16, 1893. The outlet from each filter has been trapped.

The surfaces were not disturbed until the middle of July, 1893, about a year after they were first put in operation. They were each raked 3 inches deep four different times, to remove clogging, between the middle of July and September 1. After September 1, they were raked regularly once a week until October 26, since which date they have been raked 3 inches deep daily. During November and December there was evidence of sub-surface clogging and each filter was spaded over 6 to 8 inches deep on several occasions. No material has been removed from either filter.

*Filter No. 12 A* contains 60 inches in depth of sand of an effective size of 0.19 millimeter, and receives the effluent of Nos. 15 B and 16 B. Since March 24 it has been scraped when clogged, but not raked. The clogged sand has been washed and replaced. The filter has been scraped on an average once in five days, and the average depth of clogged sand removed was 0.24 inch. Sub-surface clogging made it necessary to spade over the upper six inches of sand after scraping on September 27 and December 12 and 27. The results are summarized beyond.

### *II. (Filter No. 19.)*

This filter is also 60 inches deep, and the sand has an effective size of 0.17 millimeter. It has received the supernatant liquid from sewage after treatment with alum (1,000 pounds per million gallons and allowed to settle four hours). Since October 23 it has been scraped after the same manner as No. 12 A. The average period between scrapings was ten days and the average depth removed was 0.47 inch. Up to December 20 the filter had twice been spaded over 6 inches deep to remove sub-surface clogging. The rate of filtration, 640,000 gallons per acre daily for six days in a week, overtaxed the capacity of the filter, which was allowed to rest for two weeks beginning December 23. The results are summarized beyond.

### *III. (Filter No. 13 A.)*

This filter was constructed on Sept. 27, 1893, and contains 60 inches in depth of sand of an effective size of 0.19 millimeter. It received the supernatant liquid from sewage which had been allowed to settle four hours. It has been scraped on an average once in six days, and the average depth removed was 0.37 inch. In December the sand was spaded over to a depth of 6 inches, three times, to remove sub-surface clogging. The rate of filtration, 480,000 gallons

per acre daily for six days in a week, overtaxed the filter, which was allowed to rest for two weeks beginning December 23. The results are summarized below.

*Quantitative Efficiency — Average Rates of Filtration.*

(Gallons per acre daily for six days in a week.)

| NUMBER OF FILTER. | JAN. 1 TO DEC. 31,<br>1893. | OCT. 1 TO DEC. 31,<br>1893. |
|-------------------|-----------------------------|-----------------------------|
| 12 A, . . . . .   | 819,900                     | 960,000                     |
| 13 A, . . . . .   | -                           | 416,300                     |
| 15 B, . . . . .   | 404,700                     | 480,000                     |
| 16 B, . . . . .   | 415,200                     | 480,000                     |

| From sewage by sedimentation and Filter No. 13 A,                          | -                           | -         | 91.3                        | 98.8      |

\* Several of the percentages in this table differ a little from those presented on page 101 of Senate Document No. 4 for 1894, owing to a slight revision of, and an extension of the period covered by, the results.

*Summary and Conclusions.*

1. Of the three methods given above for the removal of sludge, filtration through coarse gravel at a very rapid rate, and with the aid of a current of air drawn through the gravel, gave the greatest purification. Furthermore, it has the advantage that it burns up the sludge to a large extent and does not call for additional means for sludge disposal.

2. The removal of sludge by sedimentation enables filters of fine material to be operated at higher rates than filters which receive ordinary sewage. It appears that it would be advisable to employ sedimentation in many large filters where the sewage is strong and the filters are not cultivated.

3. The aid received from the removal of sludge by chemical precipitation does not appear to be sufficient to justify the additional cost.

4. Of the three filters of fine sand which receive sewage from which the sludge has been partly removed by different methods, No. 12 A received the best purified sewage and gave the highest efficiency both from a qualitative and a quantitative point of view. This filter also is the only one capable of continuing to work at the rates given above.

5. Upon studying the several methods of obtaining a well purified effluent from sewage we find that the average rate of filtration for the combined area of Filters Nos. 12 A, 15 B and 16 B was 320,000 gallons per acre daily for six days in a week. This is the best result yet obtained with the experimental filters, and this system of double filtration with the aid of a current of air appears to be capable of application to the purification of sewage on a large scale.

#### SUB-SURFACE APPLICATION OF SEWAGE.

*Filter No. 7.* — This filter contains 44 inches in depth of mixed coarse and fine sand of an effective size of 0.35 millimeter, above which are 10 inches of loam and 6 inches of soil. The sub-surface drain pipe is 6 inches in diameter, with open joints every 2 feet, and is 18 inches below the surface. This pipe became clogged and on April 20 was taken up and cleaned. The sludge removed contained 75 per cent. of the insoluble albuminoid ammonia applied since the pipe was cleaned and relaid in October, 1892. The pipes were again relaid July 8 and sewage applied at the rate of 40,000 gallons per acre daily for six days in a week. The drain pipe is gradually becoming clogged, and since December 1 the full dose could not be applied.

The nitrification was incomplete in August, and the ventilation has been increased by aspiration since September 1. The quality of the effluent has improved and remains very satisfactory.

From the experiments upon Filter No. 7 and observations upon

the sub-surface filters at Lenox and Wellesley we may draw the following conclusions:—

1. From a chemical and biological point of view no marked difficulties attend the purification of sewage applied beneath the surface.

2. As much of the sludge as possible should be removed from the original sewage by screens and sedimentation before applying it to the sub-surface.

3. The sub-surface pipes should be provided with outlet gates at the lower end, opposite the point of application, so that they may be flushed out from time to time to remove the accumulated sludge.

4. In most cases, to avoid clogging, the drain pipe should be surrounded with stones or coarse gravel, and in order to prevent the sand from filling the spaces the gravel should be surrounded with successive layers of material of intermediate and gradually decreasing size.

#### EXPERIMENTS WITH SAND CLOGGED BY SEWAGE.

*Filter No. 11A.*—This filter was filled in April, 1892, with 5 feet of material which had been scraped from the surface of Filter No. 6 because it was clogged. Aided by a current of air it began to do good work in a few months and in 1893 it filtered sewage at the rate of 60,000 gallons per acre daily for six days in a week with an effluent as well purified as that from some filters of clean material. The purification fell off in the summer, owing to clogging at the surface. In August the upper 3 inches were removed and the quality of the effluent steadily improved and remained satisfactory throughout the year.

This experiment offers a strong confirmation of the conclusion already drawn with regard to the injurious effect of the presence of layers of unlike material in a filter. (Compare Annual Report for 1892, pages 403 and 409, and also the sections in the present Report on the construction of trenches and the addition of new material, pages 417 and 420.) This material, just before its removal, and when it formed a portion of the upper layer 2 inches in depth of Filter No. 6, remained saturated with water and ventilation was precluded because the cleaner sand beneath it was unable to draw the water from it. When placed by itself, however, it drained, allowed air to enter the pores and oxidation processes in time became re-established. In Filter No. 11 A the upper portion eventually contained so much stored organic matter that it remained saturated and the

comparatively clean but actually dirty and partly clogged sand beneath it could not withdraw the water from its pores to allow the entrance of air. There is no reason to believe, moreover, that this portion which was removed would not in time make an efficient filter if placed by itself. This experiment with others shows that the clogging of a sewage filter does not mean the storage in the material of any definite amount of organic matter, but that it arises from differences in capillary attraction of adjoining layers. While it is true of course that increased storage of organic matter means increased capillarity, it is also true that marked differences in capillary attraction occur in unlike material containing very little or no organic matter.

#### THE EFFECT OF POLARITE IN A FILTER ON THE REMOVAL OF COLOR FROM SEWAGE CONTAINING DYE STUFF.

*Filter No. 14.*—This filter has contained since Jan. 21, 1893, a layer of polarite\* 7 inches deep, the top of which was 6 inches below the surface. From February 13 to March 22, Patent Blue† equivalent to 0.33 part per 100,000 was put into the sewage, which was applied to the filter at the rate of 160,000 gallons per acre daily for six days in a week. The effluent was slightly colored after a few days, and the color became quite marked at the end of 38 days. The filter was then operated as usual without the dye stuff in the sewage and it was not until August 26 that the effluent became free from the color which had been stored in the filter.

During this time Filter No. 13, of the same construction as No. 14, without polarite, received the same treatment as the latter. The effluent of each was uniformly well purified with high nitrification.

Beginning on August 26, Scarlet 2R (another aniline dye), equivalent to 0.44 part per 100,000, was added to the dose of each filter. The applied sewage had a strong red color. On the second day the effluent of No. 13 (without polarite) showed a pink tint and

#### \* Analysis of polarite by Professor Roscoe:—

|                                          |        |
|------------------------------------------|--------|
| Magnetic oxide of iron, . . . . .        | 53.85  |
| Alumina, . . . . .                       | 5.68   |
| Magnesia, . . . . .                      | 7.55   |
| Water, with a trace of carbon, . . . . . | 5.41   |
| Silica, . . . . .                        | 25.50  |
| Lime, . . . . .                          | 2.01   |
|                                          | <hr/>  |
|                                          | 100.00 |

† Trade name for an aniline dye.

contained about 20 per cent. of the color in the applied sewage on the twelfth day of the application. The first appearance of color in the effluent of No. 14 was on the twenty-second day, and the color had not become marked on the twenty-eighth day, when the application of this dye was stopped.

On September 24 Patent Blue was added to the dose of each filter (0.33 part per 100,000 — the same as applied to No. 14 during the winter months), and the effluent of No. 13 was strongly colored on the first day, while that of No. 14 was tinted only very slightly.

### THE REMOVAL OF BACTERIA.

The number of bacteria in the effluent of a sewage filter depends upon the size of the material and the condition of the filter. With filters of very fine sand such as Nos. 2 and 4 it is probable that no bacteria pass through from top to bottom. When the nitrification is very incomplete and there has been considerable storage of organic matter in the sand, the number of bacteria in the effluent frequently increases. These bacteria, however, belong to one or more hardy species which are able to multiply within the filter. Thus, in the case of Filter No. 2 in March, 1893, the bacteria in the effluent were comparatively high and were nearly a pure culture of a liquefying, fluorescent bacillus.

Filters Nos. 6 and 9 A, when operated under the most favorable conditions, appear to allow no bacteria to pass through from top to bottom. When operated at high rates of filtration, however, a very small percentage of the applied bacteria, as a rule, passes through the filters.

With materials as coarse as those in Filters Nos. 1, 5 A and 15 B there are always some bacteria which pass directly through the filter. The number of bacteria decreases as the distance from the point of application to the underdrains and the time taken to travel this distance increases.

With regard to seasonal effect, it is to be stated that generally speaking the winter months are the time of least efficiency, because the conditions for nitrification and other processes are then least favorable. When a filter is in good condition it is possible to obtain normal bacterial results in the winter, and as most increases in the number of bacteria in the effluent come from disarrangements of the functions of the filters, periods of unusually low bacterial removal may be found at all times of the year.

## WORK OF THE FILTERS FOR 1893.

The experimental filters used during 1893 for sewage purification have been mainly the ones which have been fully described in previous Reports of the Board. In the following table are given the descriptions of the materials used. This is followed by an outline of the history of each filter and the monthly averages of the analyses.

*Construction of Experimental Sewage Filters studied in 1893.*

| NUMBER OF FILTER. | DIMENSIONS OF FILTERS.    |                           |                               | SIZE OF SAND.                                             |                                                           | Manner of Filling.                                                                       | In Operation since— | REMARKS.                                                                     |

## FILTER No. 1.

At the beginning of the year the surface of this filter, unprotected from the weather, was considerably clogged by organic matters stored in the sand, and during the extreme cold weather of January the nitrification was very slight, while the ammonias in the effluent became exceptionally high. The applied sewage, equivalent to 120,000 gallons per acre daily for six days in a week, at times disappeared very slowly and in a few instances froze to the sand. In this case the ice was removed with a pick and shovel in order to keep the filter in action. In February the quality of the effluent improved somewhat, but was still poor, owing to imperfect ventilation and probably to the passage of the sewage through portions of the filter where there was the least frost. From March 8 until the middle of April, ventilation was increased by drawing air through the sand by means of an aspirator attached to the outlet pipe, the end of which was trapped. The quality of the effluent improved until about the first of May, when the spring rains caused the surface to be partially covered for several days, but then began to deteriorate, and on May 5, 4 inches of discolored and partially clogged sand were removed and 9 inches of fresh material were added to bring the filter up to its original depth of 63 inches. Nitrification soon became high and remained so during the summer in the absence as well as in the presence of aspiration. The ammonias in the effluent became low and it is to be stated that in July and August the albuminoid ammonia was caused in part by the presence of small white worms which appeared to live in the underdrains. During the warm weather there was a removal, by nitrification, of considerable organic matter which had been stored in the sand. In October the ammonias began to increase in the effluent, owing to the interruption in the ventilation caused by clogging, at the junction of layers of old and new sand. On December 2, the surface was spaded over, 12 inches deep, in two layers of 6 inches each. The quality of the effluent improved up to the middle of the month, when the very cold weather interfered with the purification, but not with the quantitative efficiency. The poorest result of the month was on December 19, when the albuminoid ammonia in the effluent was .2260 part. The cause of this doubtless was that the sewage passed through holes in the frost made at the points where the warm sewage first reached the sand.

Sewage applied, 600 gallons, 6 times a week, from January 1 to July 8; 150 gallons, 12 times a week, from July 10 to August 31; 200 gallons, 12 times a week, September 1 to 16; 300 gallons, 12 times a week, September 18 to December 1; 600 gallons, 6 times a week, December 2 to 23; 300 gallons, 6 times a week, to December 31. Experiments interrupted by high water, May 5 to 8. May 5, 4 inches dirty sand removed from surface. May 11, 9 inches of new sand put on surface. December 2, 6 inches of sand taken off; next 6 inches turned over, upper 6 inches replaced and mixed with sand below. Air drawn through sand 15 minutes daily, from March 6 to 17; 12 hours daily, March 18 to April 15; 6 hours daily, May 11 to July 10; 3 hours daily, July 31 to September 1. Surface raked about 1 inch deep each week. During the winter months snow was removed 17 times (total depth, 62 inches); ice removed 11 times (total depth, 7.5 inches).

**FILTER No. 2.**

This filter of fine sand was badly clogged at the surface at the beginning of 1893, and although protected by a canvas cover and continuing to give an effluent of excellent quality it could filter but a very small amount of sewage. During January and February the sewage repeatedly froze to the sand and the ice was removed with a pick. The ammonias in the effluent were very low, but nitrification gradually decreased and there was a considerable storage of organic matter in the sand. On March 4 two circular trenches two feet deep and one foot wide, one and a half and five feet, respectively, from the edge of the filter, were constructed. These trenches were filled with No. 9 sand, as is described on page 417, and covered with boards until April 1. The applied sewage equivalent to 40,000 gal-

lons per acre daily for six days in a week disappeared promptly. The ammonias and the nitrates steadily increased until May, after which the ammonias steadily decreased and the nitrates remained high during the entire summer, indicating a removal of much organic matter from the sand. The grass and weeds which grew luxuriantly around the edges of the trenches were cut on July 20 and August 31. The dose was increased September 1 to 60,000 gallons per acre, and the filter continued to do excellent work until the latter part of October, when the trenches began to clog and the increasing free ammonia in the effluent indicated that the ventilation was imperfect. The upper two inches of discolored and partially clogged material were removed from each trench on October 30 and replaced with new sand. This did not restore the efficiency of the filter, owing to a clogging at the bottom of the trenches, which was remedied on December 2 by putting in several layers of mixed coarse and fine sand, as is described on page 417. On December 4 the trenches were covered with boards. This treatment restored the quantitative efficiency of the filter, and the quality of the effluent steadily improved.

*Effluent from Filter No. 2.*

Sewage applied twice in January, four times in February; 400 gallons 3 times a week, March 1 to 15; 200 gallons 6 times a week, March 15 to August 31; 300 gallons 6 times a week, September 1 to December 31. Surface protected by canvas cover until March 4. Trenches protected by boards from March 4 to April 1, and from December 4 to 31. Experiments interrupted by high water May 5 to 8. Two trenches dug 2 feet deep and filled to within 3 inches from top with No. 9 sand March 4. October 30, 2 inches of dirty sand removed from trenches and replaced by clean material. December 2, coarse sand and 2½ inches of fine sand removed from trenches and replaced by mixed coarse and fine for 5 inches, and then filled with coarse. Surface of trenches raked 1 inch deep each week. Grass and weeds cut July 20 and August 31. Ice removed January 11, 18, 31 and February 24.

## FILTER No. 3 A.

In January the prescribed dose, equivalent to 60,000 gallons per acre daily for six days in a week, was taken with some difficulty, owing to the accumulation of organic matter at and near the surface. The quality of the effluent was poor and became worse, although the quantitative efficiency was satisfactory in February. In March the ammonias in the effluent began to steadily decrease, but the free ammonia was still very high. Nitrification slowly improved and became very high in June and July, when there was considerable removal of organic matter stored in the sand. The effluent was well purified. Early in August the surface sand became clogged so that the sewage remained on the surface for twenty-four hours. On August 14 the surface was spaded over, corresponding to ploughing, to a depth of six inches, after which the applied sewage disappeared promptly. Ventilation was restored and the quality of the effluent, which had begun to deteriorate, became good again, with the nitrates very high at the end of the month, when the experiment was discontinued.

Sewage applied, 300 gallons 6 times a week. Experiments interrupted by high water May 5 to 8, and May 18 and 19. Surface raked about 1 inch deep each week. Air drawn through sand 15 minutes daily March 13 to 17; 12 hours daily March 18 to April 15. August 14, surface spaded 6 inches deep. Snow and ice removed January 5, 6, 7, 10, 12, 14, 16, 17, 20, 24, 25, 30, 31; February 2, 3, 4, 6, 13, 14, 18, 21, 22, 24, 27, and March 1 and 4.

## FILTER No. 4.

This filter of fine river silt with a large trench of coarse sand and covered with canvas was able to filter sewage at the average rate of 40,000 gallons per acre daily for six days in a week until the early part of March. The ammonias in the effluent were very low, but the nitrates decreased steadily and there was a large storage of organic matter in the sand. To remove the clogging the upper 2 inches of coarse sand in the trench were removed on March 6. This did not remedy matters and on March 11 the canvas cover was removed, the coarse sand dug out of the trench and about  $\frac{1}{2}$  inch in depth of clogged fine sand at the junction of the coarse sand of the trench with the fine sand of the filter scraped off; and the coarse sand was replaced after raking the fine sand to a depth of about 1 inch. This treatment did away with clogging until the last of May. During this time the nitrates and ammonias in the effluent increased. The trench failed to take the sewage promptly toward the last of May and on June 2 a new trench was constructed. The average rate was reduced June 2 to 30,000 gallons per acre daily and the quality of the effluent steadily improved until the last of September, when the purification was excellent. The grass and weeds were cut on August 31. Toward the latter part of October the new trench became clogged and it was allowed to rest and the old one used during the rest of the year. The nitrification decreased in December, although the effluent was very free from organic matter. While the effluent contained but a comparatively small amount of albuminoid ammonia throughout the year, it is to be stated that there was a continual storage of organic matter in the sand.

*Effluent from Filter No. 4.*

Sewage applied, 400 gallons, 3 times a week until May 12; 200 gallons, 6 times a week, May 13 to June 1; 300 gallons, 3 times a week, June 2 to December 22; 150 gallons, 6 times a week, December 22 to 31. Surface protected by canvas cover till March 11; tank covered with boards, December 4. Experiments interrupted by high water, May 5 to 8 and May 18 and 19. Surface of trench raked about 1 inch deep each week. May 6, 3 to 4 inches of turf removed from surface outside of trench. July 31, entire surface raked over. March 6, 2 inches of dirty sand removed from trench. March 11, coarse sand taken out and replaced after scraping ½ inch from fine sand. June 2, a new trench dug 1 foot inside of old trench, 1 foot wide and 2 feet deep, and filled with coarse sand. New trench used June 2 to October 30. August 31, grass and weeds on surface cut.

**FILTER No. 5 A.**

This filter of fine gravel stones without sand received sewage in January and February in single doses equivalent to 120,000 gallons per acre daily for six days in a week. The surface was unprotected from the weather and with a few exceptions the sewage disappeared promptly. The nitrification was incomplete and the ammonias in the effluent were very high. This was probably owing to a certain extent to the passage of the sewage through the portion of the filter near the point of application and where there was the least frost. In March the quality of the effluent improved, owing in part to the fact that the sewage was applied in three doses daily, and partly to increased ventilation by aspiration. In April, without aspiration, the effluent continued to improve in quality, and in May there was a removal of organic matter from the sand. The filter became clogged

in the early part of June, at a point just below that reached in the weekly raking, to a depth of 1 inch. This was remedied by raking to a depth of 2 inches. The purification was very good for this material in July and a part of August; but sub-surface clogging appeared again in September, and the surface was spaded over, 6 inches deep, corresponding to ploughing, on September 15. On October 30 the rate was increased to 160,000 gallons per acre daily, applied in eight doses daily for six days in a week, and there was no marked deterioration in the quality of the effluent until the last of November, when the filter became clogged again beneath the surface. Two inches of discolored and partially clogged gravel were removed on December 2, and the surface spaded over, 6 inches deep. In December the applied sewage, equivalent to 120,000 gallons per acre, was taken readily, but the nitrification was incomplete and the ammonias in the effluent were very high during the maximum flow.

Sewage applied, 600 gallons, 6 times a week until March 6; 200 gallons, 18 times a week, March 7 to October 28; 100 gallons, 48 times a week, October 30 to December 2; 600 gallons, 6 times a week, December 2 to 11; 300 gallons, 12 times a week, December 12 to 14; 600 gallons, 6 times a week, December 15 to 22; 300 gallons, 12 times a week, December 23 to 31. Experiments interrupted by high water, May 5 to 8 and May 18 and 19. Surface raked 1 inch deep each week. June 12, surface raked 2 inches deep. Surface spaded 6 inches deep September 15 and December 2. Two inches dirty gravel removed from surface December 2. Air drawn through sand fifteen minutes daily, March 6 to 18; two hours, three times daily, May 8 to September 1. Snow removed during the winter months 23 times (70 inches total depth); ice removed 9 times (2.9 inches total depth).

## FILTER No. 6.

This filter, 44 inches in depth of mixed coarse and fine sand and unprotected from the weather, received sewage at the beginning of 1893 at the rate of 70,000 gallons per acre daily for six days in a week. Owing to a storage of organic matter in the surface sand the sewage on very cold days froze to the sand, and it was necessary to omit some doses in January and to remove the ice in places with a pick and shovel in order that the filter might be kept in action. Nitrification was very incomplete in January and the ammonias in the effluent were high. The quantitative efficiency was satisfactory in February, but the effluent deteriorated in quality, owing, in part, to the fact that the oxidation and nitrification functions were thrown out of adjustment by the unfavorable conditions of the preceding weeks, but chiefly to the passage of the sewage through holes in the frost. In March and April the filter steadily improved, while from May to August, inclusive, the effluent was very well purified and moreover there was a removal of a large amount of organic matter which had been stored in the sand. On July 11 the quantity of sewage applied to the filter was increased to 90,000 gallons per acre daily. Surface clogging appeared early in September, and on September 25 the upper 2 inches of discolored and partially clogged sand were removed and replaced with fresh material. The filter did good work again until the last of November, when a clogging occurred at the junction of the old and new sand, as is described on pages 413 and 414. This was remedied on December 2 by spading the surface to a depth of 6 inches. A canvas cover was put on December 4. The purification was quite incomplete during the first half of December, but there was a gradual improvement during the last half of the month.

*Effluent from Filter No. 6.*
